**Problem of Habitual Abortion.**—Kneer says that, although many factors have been suggested as possible causes of habitual abortion, in many cases it proves difficult to find a satisfactory explanation. In this paper he reports investigations on 110 women who were subject to habitual abortion. Among this number there were only eight in whom anatomic changes on the genitalia gave a satisfactory explanation for the repeated abortions, and in another woman it appeared probable that a mitral insufficiency was the cause of repeated abortions. In the others the examination at first revealed nothing that would explain the repeated abortions. However, investigations on the menstruation revealed that a considerable number of the women, particularly those who habitually aborted during the first few months of pregnancy, had disturbances of the ovarian function, particularly in the formation of the corpus luteum. Others again had a habitus which suggested secretory disturbances and some of them had also a genital hypoplasia. The author shows that in another group of cases the inferior biologic character of the fetus is responsible for the abortion; it appears that in these cases the expulsion of the fetus is a manifestation of a biologic self protection of nature. Such a possibility must be taken into consideration, particularly in abortions that take place after the fourth month of gestation and in cases in which the parents are related. In this connection the author cites cases of women who in first marriages had given birth to healthy children, whereas in second marriages, with men to whom they were related, they were subject to habitual abortion. The author admits that in this report he failed to mention vitamin deficiency, heterogenic character of blood groups and other factors which have been mentioned as possible causes of habitual abortion. He says that in the material under consideration there was no definite proof that the latter factors had assumed a causal role in the habitual abortions.

**Serum Phosphatase in Diagnosis of Cancer.**—Albers directs attention to the fact that the phosphatase content of the blood of patients with cancer is different from that of normal persons. In order to determine whether these changes have diagnostic value he determined the phosphatase values in the serum of eighty-six patients with cancer and of forty-one control persons. He employed the method of Jenner and Kay, which is based on the phosphatase activity of the plasma; that is, on its ability to hydrolyze sodium beta-glycerophosphate. The author found that in cases of carcinoma the phosphatase values of the serum are generally increased. Since the determination of the phosphatase values alone is not adequate for the diagnosis of cancer, he decided to test the mechanisms of activation and inhibition as well. For the activation he employed a magnesium chloride concentration and for inhibition a calcium lactate concentration. It was found that the

activation was increased in the presence of cancer, whereas the inhibition showed no noticeable differences when compared with that of the controls. In most of the disorders found in the controls, the phosphatase values were low. However, jaundice, ulcers of the gastrointestinal tract and pulmonary tuberculosis were exceptions. In nonmalignant tumors and tumor-like diseases the phosphatase values varied. Two cases associated with lymphogranuloma and two with benign tumors revealed high phosphatase values and increased activation, whereas in sarcomas and leukemias the phosphatase values were low. In utilizing the phosphatase activity of the serum and its activation or inhibition as the basis of the diagnosis of cancer, the author considered as positive those serums in which the phosphatase values were in excess of 17 units or the activation was at least 60 per cent; as negative those serums in which the phosphatase values were below 16 and the activation was less than 60 per cent. The values between 16 and 17 units and the activation between 55 and 60 per cent were regarded as doubtful. The tables indicating the phosphatase values of the examined serums show 85 per cent of positive (that is, correct) results in the cases with carcinoma and 69 per cent negative (that is, correct) results in the controls. In cases of carcinoma associated with established metastatization the correct results were 97 per cent. Cases of jaundice, gastrointestinal ulcer and tuberculosis were excluded from these estimates.

**Leptospirosis in Australia.**—Walch-Sorgdrager and his associates state that cases of leptospirosis have been reported from three different parts of Australia from the districts of Ingham, Pomona and Brisbane. In each district the spirochetosis had its peculiar aspect and causal agent. In the Ingham district spirochetosis occurs endemically with epidemic aggravations among cane cutters. Mild and serious cases were observed there with and without jaundice, and among the latter group there were some fatal cases. Ballica and Zandoni strains were found to be the causative agents and the first of these proved to be a new kind of leptospira; the second, although reacting with the Salinem group, should probably be regarded as a separate strain. Both strains were found also in the rat. In Pomona, cases of a mild, seven day fever occur every year. In one case the Pomona strain was cultivated, a strain which has not been described before and which has its own antigenous nature. In Brisbane three cases of leptospirosis were described, two of which concerned sewer workers. These were classic cases of leptospirosis icterohaemorrhagica. The author discusses some of the difficulties that were encountered in connection with the classification of the Zandoni strain. Serologic tests on the Zandoni and Salinem strains indicated that in their antigenic structure these two strains are partly identical. However, further studies will be necessary to decide whether the Zandoni strain belongs to the Salinem group or not. The authors think that for the present the Zandoni strain should be designated as Australis B, the term applied to it by Lumley.

# Vitamin C in Tuberculosis of Bones and Joints.—

Warns reports studies on twenty-six patients with tuberculosis of the bones and joints. Sixteen of these patients had spondylitis, four had coxitis, five had gonitis and one had a clavicular

tuberculosis. Six had at the same time tuberculosis of other parts of the skeleton. Vitamin C was administered to these patients by mouth in the form of tablets, each of which contained 50 mg. of a synthetic ascorbic acid. At the onset the dose was 250 mg. for adults and for children over 6 years of age; it was 150 mg. for children less than 6 years of age. As soon as the urinary concentration reached more than 5 mg. per hundred cubic centimeters, the dose was decreased to 50 mg. a day. The saturation with the vitamin C was continued for four and one-half months. A therapeutic action on the tuberculous process could not be detected; however, it seemed that the general condition was slightly improved. Like other investigators, the author observed that patients with tuberculosis have greatly increased vitamin C requirements, their daily consumption being from three to five times as much as in healthy subjects. Moreover, there seems to be a certain parallelism between the quantity consumed and the activity of the process.

**Injection Therapy of Varices.**—Mårtensson says that the immediate results of the injection therapy of varicose veins are generally regarded as good but that the opinions on the later results differ greatly. With the aid of the Trendelenburg-Berntsen test, which gives exact information about the changes in the cutaneous veins, the author made observations on 102 patients with progressive insufficiency of the veins of the legs, all of whom had been subjected to ambulatory injection therapy. In the course of these control tests, which extended over a period of three years, the author found that the relapses occurred only in cases in which immediately or soon after the blockage a centrifugal venous current developed on the level with or proximally to the thrombus. The relapses originated from destruction of the thrombosis and the recanalization or formation of a passage as well as from the refilling of veins that had not been thrombosed but only collapsed. The refilling with blood was effected by a remaining proximal portion of an insufficient vein either directly or by way of an insufficient collateral. Relapses developed in all cases (fifty-five in all) in which the insufficiencies of the veins of the lower leg extended above the lower third of the thigh. The relapses occurred earlier and were more extensive in cases in which only a small portion had been blocked than in cases in which blockage had been as extensive as possible. The varying degrees of venous insufficiency seemed to make no difference in this respect. All relapses developed between one and eighteen months after completion of the treatment. The relapses generally resulted in a greater or lesser extension of the insufficiency; it was most pronounced in cases of partial blockage and in three cases it was followed by the development of new varicose ulcers. Relapses did not occur in forty-five cases in which the venous insufficiency was restricted to one or two branches of a vein. Histologic studies in these cases revealed that the factors favoring relapses are completely eliminated. Moreover it seems that, if the injection therapy is executed properly, the further extension of the venous insufficiency can be arrested at least for a while (time of observation). In these cases the injection treatment was easy and did not result in complications. On the basis of the results of this study the author concludes that cases in which the venous insufficiency is restricted to venous branches in the lower part of the leg (all early cases of varices) require only injection therapy, provided of course that the injection treatment is not contraindicated by other disorders. In all other cases, that is, in those in which the insufficiency of the veins has been extended to the thigh, the combination therapy according to De Takáts-Quillin should be employed. In some cases in which the exact differentiation is difficult, the injection treatment should be followed by the combination therapy.

## THE RATIONAL TREATMENT OF ACUTE HEMATOGENOUS OSTEOMYELITIS

J. ALBERT KEY, M.D.

ST. LOUIS

The clinical picture and laboratory observations in acute hematogenous osteomyelitis are so well known to the average physician that a discussion of the diagnosis in this paper is not warranted. However, in a large percentage of the cases the diagnosis is not made until late in the disease. This is because the general practitioners and pediatricians who see the early cases are not osteomyelitis conscious. Consequently I would like to emphasize the facts that when a child suddenly becomes ill with fever and presents evidence of pain, disability and localized deep tenderness in an extremity osteomyelitis should be considered, and a negative x-ray examination does not rule out this disease.

This paper is presented because the disease is relatively frequent and not only carries a high mortality but usually causes prolonged illness in many of those who survive the acute attack and is an important factor in the production of crippling. While most surgeons have definite ideas as to the proper treatment of acute osteomyelitis, the treatment advised by authorities on the subject varies from that of the radical group, who recommend immediate emergency operation with adequate drainage of the focus in the bone, to that of the conservative group, who treat the patient for the general infection and more or less ignore the focus in the bone with the expectation that, as the patient's resistance is increased, the local disease will either heal spontaneously or form a subcutaneous abscess which can be drained by a small incision. There are, of course, all gradations between these two extremes, and a rather extensive study of recent literature leaves one very much confused. It is thought, then, that a rational consideration of the disease may tend to harmonize some of the wide differences of opinion.

The disease is caused by pyogenic bacteria which enter the blood stream from some focus (demonstrable in about 20 per cent of the patients) or are present as causal organisms in the blood stream and localize in the bone and begin to multiply. More than 90 per cent of the cases that occur are in children and it is generally believed that the usual site of the primary infection in the bone is in the metaphysis near the epiphyseal line.

In infants under 2 years of age the offending organism is a hemolytic streptococcus in about half of the cases and a staphylococcus in almost all of the remainder. In children over 2 years of age about 90 per cent of the cases are due to *Staphylococcus aureus*, and the streptococci account for most of the remainder. Either of these organisms may kill the patient promptly by an overwhelming general infection or more slowly over a period of weeks or may lead to prolonged suppuration with necrosis of bone, or an abscess may form which drains and heals or which heals without drainage.

It is thus obvious that there may be wide variations in the course and prognosis of individual patients, each of whom is suffering from an acute hematogenous osteomyelitis. These are due to that poorly understood condition which may be called the relation of the patient's resistance to the virulence of the organism. An increase in the patient's resistance or a decrease in the virulence of the organism will tend to cure the disease, and the converse also is true. Consequently, since "the first duty of the physician is to do no harm," care must be taken not to do anything to lower the patient's resistance even temporarily unless sufficient benefit will accrue to justify the procedure. It is accepted that an operation tends to lower the patient's resistance temporarily and that the ill effects vary directly with the amount of blood lost, the extent of the operation, the time consumed in performing it and the duration of the period of anesthesia.

The pyogenic cocci are characterized by their invasive qualities and by their ability to kill the tissues which they invade. This ability to spread into and kill the surrounding tissues is most evident when the focus is confined in the tissues and is relatively slight when the focus is on a surface or is adequately drained so that the growth of the organisms and the reaction of the tissues cannot generate pressure.

In the subcutaneous tissues infection with pyogenic cocci results in an acute inflammation. As the bacteria increase in number the adjacent cells are killed, autolysis occurs and pus is formed. The extravasation of fluid in the tissues, the dilatation of the blood vessels and the accumulation of phagocytic cells, especially leukocytes, and the proliferation of connective tissue cells cause swelling and tend to wall off and localize the infection. When the process occurs in a nonexpansible compartment, such as a bone, the changes mentioned are inhibited and the bacteria are enabled to invade and destroy the surrounding tissues with greater facility. It is also to be noted that in the subcutaneous tissues pain and tenderness occur early, while in the bone the focus is silent until the inflammation has reached the periosteum, because the interior of the bone is devoid of sensation, as can be demonstrated by infiltrating the

Read before the Section on Orthopedic Surgery at the Eighty-Ninth Annual Session of the American Medical Association, San Francisco, June 17, 1938.

periosteum with procaine hydrochloride and drilling through the bone without causing pain.

It is thus apparent that by the time the infection causes pain and local tenderness the inflammation has spread through the cortex to the periosteum and that early drainage of the focus in the bone is desirable in order to inhibit the spread of the infection in the bone and the resultant extensive necrosis of bone. Early drainage of the focus in the bone is desirable not only because it tends to limit the local spread of the infection in the bone but also because it tends to cut off the supply of organisms at its source.

This brings up the question as to what is meant by the terms bacteremia and septicemia. I formerly considered bacteremia a condition in which bacteria were being fed into the blood stream from a focus and were being destroyed at about the same rate as that at which they entered the blood; the term septicemia I applied to a more severe condition in which the bacteria were actually multiplying in the blood stream. This distinction was purely theoretical and has been abandoned; and the two terms are used interchangeably to refer to a state in which bacteria enter the blood stream more rapidly than the defense mechanisms of the organism can destroy them, and it is probable that in certain instances the blood serves as a culture medium and the organisms actually multiply in the blood stream.

The source of the organisms in the blood stream is not an academic question but is of great practical importance because it determines the therapy in acute osteomyelitis. A large number of otherwise competent observers hold that since the bacteria reached the bone through the blood stream the patient is suffering primarily from a general infection and that the focus in the bone is merely incidental and should be ignored while the physician directs his therapy to the general infection. I have no patience with such reasoning. These patients were not sick until the focus developed in the bone, and they are now sick because they have a spreading infection in the bone which is feeding toxins and possibly bacteria into the circulation. If they have a demonstrable primary focus this merely served as a means by which a few bacteria got into the blood stream. It is not to be thought of as a funnel pouring a steady stream of bacteria into the blood. Had these few bacteria been taken care of in the usual way, nothing would have happened. But when some of them settled in the bone and started a spreading infection the disease began.

It is thus evident, I believe, that the local lesion should be drained. The next question is When should it be drained? It is argued that in the early stages the condition in the bone is analogous to a spreading cellulitis and that it is a fundamental principle of surgery not to incise a spreading cellulitis but to immobilize the part and apply local heat until the infection has localized and local tissue immunity has been established. By local immunity is meant a local concentration of opsonins which affect the bacteria in some manner and render them susceptible to the phagocytes. I do not believe that it has been established that there is sufficient local concentration of antibodies around a pyogenic infection to be of clinical importance. It is my impression that the localization of a pyogenic infection is an anatomic rather than an immunologic phenomenon and that it is due to the concentration of leukocytes and connective tissue cells and to the mechanical factors of vascular dilatation, edema and thrombosis. In a nonexpansile compartment, such as bone, there is con-

siderable difficulty in the mechanical walling off of an infection, and the thrombi become septic and aid rather than hinder the spread of the disease.

While I do not recommend it, I do not believe that any particular harm is done by incising an area of cellulitis provided the tissues are not unduly traumatized and the part is treated properly afterward. In draining a deep abscess one incises through normal tissues and then a zone of cellulitis and is not concerned with the possibility of opening up blood or lymph channels that will permit the infection to reach the blood stream, nor is one concerned that the organisms from the deep abscess will invade and destroy the overlying normal tissues which have not established a local immunity. When the infection is in a tendon sheath or a joint it is drained immediately and one does not wait for these structures to be destroyed while the patient's resistance is increased to a point at which an equilibrium between it and the infection is established. Why should it be different in bone?

Furthermore, it is to be noted that infections in bone are not seen by surgeons as early as are severe infections in soft tissues, because the focus is silent until it spreads through the bone to the periosteum where it can affect sensory nerves and because the physicians who see them early are not osteomyelitis conscious and do not make the diagnosis early. In a series of 200 consecutive patients with chronic osteomyelitis who were admitted to the Shriners' Hospital for Crippled Children in St. Louis, Dr. McCarroll and I found that forty-one in whom an incorrect diagnosis had been made had been under treatment for from one to twelve weeks and that only nine had had the bone drained during the first week of the disease. It is thus evident that relatively few of these patients enter the hospital or are seen by a surgeon during the early stages of their illness, and the abscess in the bone is usually well established when they enter the hospital.

The question then arises as to whether they should be operated on immediately or treated conservatively. It is obvious that in a disease which varies so greatly in its severity and in its course the treatment cannot be standardized and that each patient must be considered as an individual problem which must be met according to the best principles of surgery.

#### CLASSIFICATION OF PATIENTS

From the standpoint of treatment, patients with acute hematogenous osteomyelitis may be divided into four overlapping groups: (1) patients with a mild infection who are not acutely ill, (2) severely ill patients with a spreading infection but in good general condition, (3) severely ill patients with a spreading infection and in poor general condition, and (4) patients in whom the infection has localized and is subsiding.

1. The treatment of patients who are not acutely ill need not be an emergency affair, but there is no reason why these patients should not be operated on and the bone drained as soon as convenient after the diagnosis is made. As a rule, these are patients in whom the infection is of relatively low grade, in whom there is very little danger that it will be widely disseminated in the bone and in whom the infection may form an abscess which can be drained subsequently or may even form an abscess in the bone which will heal spontaneously if they are left alone. On the other hand, if these patients are not treated a localized chronic osteomyelitis may develop which will demand radical treatment.

Consequently, I think it advisable to operate on such patients and drain the focus in the bone early in order to prevent the probable later chronic disease.

2. The severely ill patients with a spreading infection of the bone with high fever and marked toxemia are those seen relatively early in the disease but who are not dehydrated and whose general condition is good. A blood culture should be taken on admission, but one should not wait for the result, because it has no influence on the immediate treatment, which should be directed to the focus in the bone. In these cases I believe that waiting is not advisable because the pyogenic organisms are characterized by their tendency to invade and necrotize surrounding tissues, and if the patients are not operated on there will probably result a widespread destruction of bone with eventual development of a chronic osteomyelitis which may be difficult or impossible to heal. In addition to this there is the danger of involvement of the joint and the development of metastatic foci of infection. There is also the definite danger that leaving the abscess in the bone will tend to the production of a septicemia.

It is to be noted that I do not consider that a patient in whom hematogenous osteomyelitis develops has a primary septicemia but I feel that the septicemia which is so frequent in this disease is secondary to the infection in the bone. In other words, the constant presence of organisms in the blood stream means that these organisms are being fed into the blood stream more rapidly than the system of the patient is able to get rid of them and does not necessarily mean that one organism has got into the blood stream and has continued to multiply. The continued presence of the infection in the bone under pressure is one of the most favorable conditions for the development and continuance of such a septicemia, and even if a septicemia is present one of the most efficient methods of combating it is to cut off the supply of organisms to the blood stream by draining the focus in the bone. In such cases I recommend immediate operation with opening of the bone as gently as possible and with as little disturbance to the patient as possible. Under these conditions I have used local anesthesia and added epinephrine to the procaine hydrochloride and have found it possible to drain bony abscesses with but little harm to the patient.

After the operation the wound should be packed loosely with petrolatum gauze and the extremity should be immobilized in a large, hot, wet dressing and splint or in a plaster-of-paris cast, and fluids should be forced, if possible, or given intravenously or subcutaneously if necessary. Sufficient morphine or other sedative should be given to relieve the pain. To severely ill patients we have usually given repeated small transfusions and have not seen harm result from them, but I doubt whether they do any particular good in acute infections when there has been no significant loss of blood from the operation and when sufficient time has not elapsed for the production of a secondary anemia by the infection. Later, if a secondary anemia develops, transfusions are indicated to restore the blood volume or replace the cells that have been destroyed, but I am skeptical as to their value in supplying antibodies to combat the infection.

In infants under 2 years of age somewhat more leeway is allowed, and the operation may be delayed for four reasons: 1. The bone is more porous and the infection can more readily pass out through the bone and form extraosseous abscesses without sequestration.

2. Infants become dehydrated and toxic very quickly and most of them are badly in need of fluids when first seen. 3. Infants do not stand surgical operation as well as do older children and adults. 4. There is about an even chance that the infecting organism is a streptococcus which is susceptible to sulfanilamide.

3. Severely ill patients not in good general condition are usually patients who have had the disease for some time and are extremely toxic, are frequently delirious, are markedly dehydrated and have a high fever and a rapid, thready pulse. There is frequently a positive blood culture on admission. On this type of patient it is unwise to operate immediately, not because it is not desirable to drain the focus in the bone but because the patient's resistance is very low and has been taxed to the breaking point by the infection. Consequently it is better to put such a patient to bed, relieve his pain by morphine and immobilize the extremity, preferably with the application of a massive hot, wet pack and a splint with traction if it is practicable to do so. Fluids should be given immediately by mouth if possible or in the form of dextrose or salt solution intravenously if necessary.

If the patient is under 2 years of age there is about an even chance that the offending organism is a streptococcus and sulfanilamide in rather large doses may be started immediately without waiting for the blood or aspiration culture. This is because infants tolerate the drug well and because we delay operating on infants under conditions in which an older child would be operated on immediately. In children over 2 years of age we do not give the drug until we have obtained a positive culture of a streptococcus, because the chances are less than one in ten that it is a streptococcus and I believe that sulfanilamide may actually do harm in staphylococcal infections. Certainly I do not like the idea of operating on patients who are cyanotic from the drug, and these patients are going to be operated on because even in streptococcal infections I do not believe that it has been shown that sulfanilamide has much effect on a focus in a bone. In my limited experience it has not cleared up such foci, though it is possible that it may have helped to localize the disease.

In addition to the foregoing, one must consider immune serum, antitoxic serum, bacteriophage and toxoids. Bacteriophage has been recommended especially for staphylococcal septicemia. However, MacNeal's<sup>1</sup> figures give a mortality rate of 70 per cent, which is about the usual mortality of staphylococcal septicemia without bacteriophage, and since bacteriophage is inactive in blood serum I do not believe that it is worth while to try it.<sup>2</sup> Toxoids and vaccines are of no value in an acute infection and of questionable value in a chronic staphylococcal infection because, as is well known, the human organism shows little or no tendency to develop an immunity to the staphylococcus. The same is true of transfusions with blood from patients who have recovered from a similar disease or who have chronic osteomyelitis. These patients do not, in my experience, carry a high degree of immunity to the staphylococcus. In streptococcal infections it may be possible to find donors with sufficient opsonins to be of value, and if laboratory facilities and sufficient donors are available they should be checked for opsonins

1. MacNeal, W. J., and Frisbee, Frances C.: One Hundred Patients with Staphylococcal Septicemia Receiving Bacteriophage Service, *Am. J. M. Sc.* 191:179-195 (Feb.) 1936.

2. Eaton, M. D., and Bayne-Jones, Stanhope: Bacteriophage Therapy, *J. A. M. A.* 103:1769-1776 (Dec. 8), 1847-1853 (Dec. 15), 1934-1939 (Dec. 22) 1934.

against the offending organism and immunotransfusions should be given as suggested by Lyons.<sup>3</sup> Robertson<sup>4</sup> used an immune serum which he believes to be of some value. It should be given intramuscularly and not intravenously, since seven of Robertson's nine patients to whom it was given intravenously died. There is a staphylococcus antitoxin on the market and it is hoped that it will be of value in detoxifying these acutely ill patients; it may be used in large doses in order to get them into condition for operative drainage. Its use is still in the experimental stage.

The question next arises as to how long one should continue conservative treatment. This cannot be stated, but I believe that one should continue such treatment a matter of twelve hours or so until the patient appears to be getting better or worse. As soon as the patient has had some sleep and rest from the morphine and immobilization and as soon as his body fluids have been restored, I think that he should be operated on whether or not an abscess is present, provided a competent surgeon is at hand to perform the operation. The point is, I regard the deferring of the operation not as an attempt to permit the infection to localize but only as an effort to get the patient into better condition for the operation. Consequently, the waiting period is a matter of hours rather than of days.

4. In the last group of patients, in whom the infection has broken through the bone and formed an extra-osseous abscess and whose acute illness is subsiding, I do not think it makes very much difference when they are operated on. However, the sooner the abscesses are drained the less likely are secondary foci to develop, although it is probable that by the time the acute condition has begun to subside there will be no further destruction of the bone. They really present a problem in chronic osteomyelitis and represent the group who have survived the so-called conservative treatment.

#### TYPE OF OPERATION

The type of operation varies with the condition found and with the age of the patient. In infants as little work as possible should be done on the bone. In children and adults it is important that adequate drainage of the focus within the bone be accomplished. It is stated that this can be done adequately by incising the periosteum. Starr<sup>5</sup> and his co-workers advocate drilling the metaphysis near and in the direction of the epiphyseal line. If one is going to expose the bone I think that it does no harm to take out a window, especially as one is taking the window from the metaphysis where the cortex is quite thin, and if one uses sharp, thin osteotomes or large drills this can be done with relatively little trauma. The cavity is not curetted and no effort is made to remove the dead bone. The operation is for drainage only and is not a sequestrectomy. This gives a much better exposure of the underlying cancellous bone and is less apt to damage the epiphyseal line. In confirmation of the likelihood of damaging the epiphyseal line by drilling according to the method of Starr, Johnson's<sup>6</sup> report of seventy-three cases in which this method was used showed that there was disturbance of growth in 55 per cent.

6. Johnson, R. A. Y.: Effect of Inflammation on the Epiphyses, *Arch. Surg.* 32: 810 (May) 1936.

In very ill patients the anesthetic should not be started until the surgeon is ready to make the incision, the operation should be as simple and brief as possible, and especial care should be taken not to traumatize the tissues unduly and a tourniquet is not applied.

After the operation the wound should be packed loosely with petrolatum gauze and the extremity immobilized either in a very large hot, wet dressing or in a plaster-of-paris cast, and the preoperative treatment just described should be continued.

In a diffuse infection in cancellous bone it is impossible to drain all of the area. Consequently, the temperature may be expected to fall gradually unless a septicemia is present. In certain cases the temperature will fall and then rise after a few days. This may be due to inadequate drainage of the primary focus, to extension of this focus or to the development of another focus. If another focus develops it should be drained as soon as it is recognized if the patient's condition warrants the operation. In cases in which drainage is established very early, and especially in those due to streptococci, the primary wound may heal without sequestration. In cases due to a staphylococcus in which there has been widespread destruction of bone there will be sequestration and chronic osteomyelitis which must be treated at a later date.

#### CONCLUSIONS

1. Early diagnosis is as important as it ever was in pyogenic infections of bone, and each case should be treated as an individual problem and according to the surgical principle that a deep abscess should be drained as early as possible provided the patient is in condition to stand the operation.

2. Not every case of acute osteomyelitis requires immediate operation, but every patient with this disease presents an acute surgical emergency and should be seen by a surgeon as soon as possible after the onset of the disease. The surgeon should decide when to drain the focus in the bone, and this decision may be a difficult one.

3. Early and adequate drainage of acute osteomyelitis is the most effective means of preventing chronic osteomyelitis.<sup>7</sup>

#### ABSTRACT OF DISCUSSION

DR. W. D. GRIESEMER, Reading, Pa.: Dr. Key has given his treatment of this disease in a complete manner. Not all men will be in complete agreement with his views. Since most of these cases occur in children, diagnosis is often delayed until a period that precludes effective early treatment. The type and severity of the infection influence the treatment. In treatment, one may run the gamut from extreme conservatism to some form of radical procedure. The latter may vary from simple incision of the periosteum to drilling the medullary cavity or to extensive chiseling operations, with removal of the diseased cortex for drainage. Extreme conservatism is supported by a number of writers. A more radical course is advocated by others. However, nothing radical is done until local suppuration is very certain. Pyogenic osteomyelitis is not considered a surgical problem until this occurs. Fulminating cases, with few localizing signs, are fatal in spite of any treatment. In these one feels equally wrong in being radical or in just standing by. However, one should not in a routine manner delay primary operation, awaiting very marked local signs. Such surgical inactivity will increase an already appalling mortality.

7. Key, J. A.: The Prevention of Chronic Osteomyelitis: Early Diagnosis and Treatment of Acute Osteomyelitis, *J. Missouri State M. A.* 33: 39-43 (Feb.) 1936.

Neither should operation be extensive as a matter of routine. Its extent should be indicated by conditions found. Conservative, intelligent, exploratory operation with due consideration of all factors appears to be the best course and certainly can do no harm. Dr. Key's paper is a contribution to the treatment of these difficult cases.

DR. JESSE T. NICHOLSON, Philadelphia: Dr. Key has presented many of the perplexities encountered in the treatment of acute hematogenous osteomyelitis. He has given a classification of cases. He has found immediate operation necessary in but one group, the severely ill with a spreading infection but in good general condition. He has emphasized the role of the local bone focus as a source of toxin and bacteria which influence the general condition of the patient. These undoubtedly would be good reasons for immediate radical operation, but the results of conservative care and delayed operation make even these points controversial. In reviewing some of the recent papers on osteomyelitis one obtains the impression that early operation is hazardous to the patient. Green and Shannon found a mortality of 45 per cent following operation in infants under 6 months, and 21 per cent for all children under 2 years. They called attention to the high incidence of streptococcal infection at this age. This type of infection results in spontaneous formation of superficial abscesses and absence of sequestrum. By treating the general infection with blood transfusions, administration of increased fluids and simple incision of the abscess when it formed, the mortality was decreased to 3 per cent. Wilson and McKeever reviewed ninety cases including children over 2 years of age. In this group the staphylococcus was the common cause of the infection. When surgical drainage was done in the first seven days there was a 25 per cent mortality and after one week 9.7 mortality; in twenty-three cases in which spontaneous drainage occurred there was only one fatality. Even more conclusive was the recent report of Henry Brown of 160 cases before the Philadelphia Academy of Surgery. In the very toxic group, in which immediate operation was done, the mortality was 34 per cent. In very toxic cases in which surgery was delayed the mortality was 11 per cent. In the group of nontoxic cases there was no difference in mortality whether operation was immediate or delayed. The autopsies in cases in which death followed early operation proved by the evidence of multiple abscesses that the surgical procedure was futile. In the presence of blood stream infection there was a 51 per cent mortality. In cases in which a secondary blood stream infection developed following operation a 52 per cent mortality resulted.

DR. JOHN C. WILSON, Los Angeles: The situation resolves itself into treatment of infection irrespective of whether or not a bone abscess is present. Dr. Key said to me "You went so far in your paper as to advise the patients not to see a doctor." I do feel that when an abscess develops it should be drained, but all are familiar with cases of osteomyelitis that are opened in the first twenty-four or forty-eight hours in which no pus is encountered. The medullary canal contains a gray or serous exudate from which a positive culture of staphylococcus or streptococcus may be recovered. Those are the cases in which drainage should not be done. Whether or not septicemia is a primary or secondary factor is beside the point. An early drainage of these infections in the bone will, if the bacterial count in the blood culture is carefully observed, cause it to rise. I have seen this happen on a number of occasions. I have been following the bacterial count from day to day, and immediately after the drainage of the abscess the number of colonies per cubic centimeter of blood is markedly increased. It is my belief that the patients should be observed at least for a short time or until one finds out how the organism as a whole is reacting to this generalized infection. Blood cultures are of value to determine whether or not the patient is reacting properly. A gradual or rapid increase in the number of organisms recovered per cubic centimeter of blood indicates very closely that the patient's resistance is low. I cannot agree with Dr. Key that incision of a cellulitis or an infection which is not localized is without danger. Incision of a brawny, indurated area of skin and soft tissue is associated with great hazard. A little later on when this area softens and an abscess is formed it may be drained with impunity. The same situation occurs in bone. When the pus is present it should be evacuated, but all are

aware that the evacuation of the abscess in the bone does not produce an immediate drop in temperature. It sometimes continues as long as six weeks after the drainage of the medullary canal before the temperature drops to normal. The plea that I wish to make is for the consideration of the patient as a whole and not of the individual bone lesion. The use of sulfanilamide has been mentioned. It probably has some place in the treatment of streptococcal infections but before using it one should know the type of organism that caused this particular difficulty. During the past year I have used immune rabbit serum in a few patients, apparently with some satisfactory results, but this must be continued for a further time before definite conclusions may be drawn.

DR. EARL D. MCBRIDE, Oklahoma City: I am seeing osteomyelitis in a much earlier stage and at a much younger age than I used to. It seems to me one ought to add just one more qualification to the type of common sense treatment. If the patient is a child in whom the abscess has already found its exit through the cortical bone but has not drained through the subfascial tissue or through the skin, it seems to me useless to expose the child to the dangers of an operation to open the bone further. One should simply drain the abscess of soft tissues under a local anesthetic and not try to do anything to the bone until a later date. After the child has regained strength, further drainage of the bone may be necessary. However, if it can be decided that the bone has not released the pressure by exit of its own accord, the bone should be drained surgically at that early stage in as cautious a manner as possible.

DR. WALTER G. STERN, Cleveland: I should like to ask Dr. Key whether he does not believe that in the stage of the disease which Dr. Wilson discussed—just before the abscess forms—if one just took a good, big, sharp, rotating burr and went into that area and out as quickly as one could, would one not, in an absolutely harmless manner, create a channel out of which the pus, when formed, may be readily drained, eliminating all tendency to back pressure and thus relieve the children of the danger of having those multiple foci that I so deplore?

DR. CHARLES F. NELSON, Beverly Hills, Calif.: The question of nutrition has been neglected in the discussion of the osteomyelitis situation. Why do these children have osteomyelitis? The reason is a developmental disturbance plus the lack of proper nutrition which is the vitamin and mineral balance. In my work on bone metabolism I have come to believe that a normal bone is never infected. Mineral imbalance probably precedes any bone disease. I have implanted staphylococci taken from cultures of osteomyelitis with septicemia into bone in animals, and the animals which have been kept on diets containing mineral and vitamin balance for a few weeks before the implantation suffered no ill effects while animals prepared on insufficient diets died. Osteomyelitis usually develops in children who are suffering from rickets or have some osteoporosis. The osteoid tissue present has almost no circulation. Without bone trabeculae there are no capillaries and this is the site where infection begins. Physicians should be reminded at once to establish vitamin and mineral balance, as marked general improvement of the child can be influenced immediately and local resistance about the foci of infection can be thrown out in a few days by the establishment of trabeculae with their accompanying capillaries. Most children with osteomyelitis have a latent tetany and their mineral balance should at once be established. I feel that the factor of developing resistance should be stressed. The question of drainage is an individual one. One should use every means of general sustenance until some definite evidence of localization has been established and then one should not be too destructive with surgical operation.

DR. J. ALBERT KEY, St. Louis: During the past year Dr. McCarroll and I reviewed 200 patients with chronic osteomyelitis who had been patients in the Shriners' Hospital, St. Louis. Of the 200 patients 50 per cent had joint involvement, 25 per cent had multiple foci, and 33⅓ per cent of the total number that we were able to treat over a period of three years were not cured at the end of three years. In other words, we cured only two thirds of those patients, and we could do anything that we wanted to with them. I may also add, for the benefit of the statistics, that we had no mortality among any of those patients, which I think is one answer to the mortality in statistics which

is seen elsewhere. Patients who enter with abscesses don't die. The patients of this group who were going to die died before they got to the hospital. The die is cast early in the disease in a certain number of persons who develop an acute pyogenic infection and there is nothing that anybody can do that will save them. There is also a group that are going to get well in spite of anything that we can do. There is a much larger group in whom we may influence the course of the disease. Early operation, if possible before pus is formed, will abort a considerable number of these cases of acute osteomyelitis, will prevent patients from getting extremely toxic and will save a lot of crippling in children. If the patient is too toxic to stand the operation, I think that one must wait until one can get the patient in as good condition as possible, not because one wants an abscess to form but because one wants to be able to operate on a patient who has a chance of surviving.

### TREATMENT OF FRACTURE-DISLOCATION OF THE SPINE ASSOCIATED WITH CORD INJURY

CLAUDE C. COLEMAN, M.D.  
RICHMOND, VA.

AND  
JOHN M. MEREDITH, M.D.  
UNIVERSITY, VA.

Injury to the cord by fracture-dislocation of the spine frequently demands that consideration be given to measures which will protect the cord from further injury by pressure of displaced bone. The impossibility of regeneration of the cord being accepted, it logically follows that the treatment of cord injuries, so far as restoration of function of the cord is concerned, is effective only in those cases in which the cord has not been entirely destroyed at the level of the vertebral lesion.

It is often stated that, because of the concussion and spinal shock associated with severe injuries to the cord produced by fracture-dislocation, it is impossible to make an early differentiation between complete physiologic interruption which may later show some recovery and a total transverse lesion which is permanent.<sup>1</sup>

It seems improbable that concussion is a factor of importance in cases of fracture-dislocation due to indirect violence. A better explanation of the instantaneous loss of function is contusion or crushing of the cord in the pia, which is rarely lacerated except in the most severe injuries. Laminectomy cannot improve the condition of the injured cord in such cases.

Compression of the cord is determined by the Queckenstedt test. The importance of this test in the study of injuries of the spinal cord was emphasized by one of us<sup>2</sup> in 1925. At this time we considered a positive subarachnoid block, demonstrated early by the Queckenstedt test, as an unequivocal indication for operation, unless the dislocation was so extensive as to show conclusively that the cord was crushed. Before the application of this test to the study of cord injuries

there was little reliable data on which the indications for laminectomy might be based, and in many cases operation was done when there was no pressure on the cord. In the absence of compression on the cord, operation is not only futile but increases the damage to the spinal column already weakened by the injury. A larger experience with the Queckenstedt test has removed an earlier optimism with respect to the performance of laminectomy in those cases in which a fracture-dislocation has been suffered with immediate loss of all function of the cord below the site of the dislocation.

Examination of the cord at operation in complete lesions nearly always shows a sleeve of pia mater enclosing a softened, pulpy mass of disintegrated cord tissue, and pressure over the contused area after incision of the dura permits the finger to palpate the body of the vertebra with no resistance other than that offered by the pia alone.<sup>3</sup> In no case in our series has compression been due to extradural or extramedullary blood clot, although gross blood in the spinal fluid has been present in about one half of the cases. In a few cases due to direct force, the laminae are fractured and may be driven in on the cord. Fractures of the laminae with displacement and compression of the cord are more hopeful as a rule than fracture-dislocation. In severe incomplete cord lesions with compression from fractured laminae, prompt laminectomy may be of great benefit.

Partial or complete recoil of the displaced vertebrae toward normal alignment is the rule in fracture-dislocation of the spine. The greatest displacement continues only so long as the displacing force is in action, and the damage to the cord is generally completed when the dislocation reaches its maximum. On partial or complete recoil of the displaced vertebrae, bony pressure is reduced and may in some cases be completely removed from the injured cord. X-ray examination after recoil can give no information as to the extent of the displacement when the force was acting, so the gravity of the lesion must be determined by the patient's history and the evidence of impairment of function of the peripheral cord.

The history which the patient with a complete lesion usually gives is that with the impact of the injury he became paralyzed and lost all sensation in the lower extremities. If examination of the patient discloses absence of the Babinski reflex, deep sensibility, tactile sensation and deep reflexes distal to the lesion, our experience indicates that the injury to the cord is a hopeless one regardless of the treatment employed. The only recovery in such cases has been the return of some segmental innervation just below the level of the injury. For some years we have considered immediate and complete physiologic interruption of the cord from fracture-dislocation produced by indirect violence as an equivalent of anatomic transection.

Unconsciousness from an associated injury to the head or the mental confusion that sometimes results from lesions high on the cervical spine may render the patient incapable of giving an accurate history as to whether the injury produced complete and instantaneous loss of function of the cord below the lesion, and in some cases in which there is no unconscious state, mental confusion may make the tests for sensory and motor impairment

unreliable. In such cases, provided there is pressure on the cord as demonstrated by the Queckenstedt test, it seems permissible to resort to operative measures to relieve the pressure, with the hope that the injury did not crush the cord and that the relief of pressure might result in some benefit to the patient. Cases of this type are unusual, but, in the absence of history indicating that the onset of paralysis was instantaneous, one may be justified in assuming that it was not immediately complete.

Spinal injuries are often overlooked in unconscious patients. The stiffness of a broken neck has frequently been attributed to the bloody spinal fluid from an intracranial injury until the persistent complaint of the patient after recovery from unconsciousness led to adequate x-ray studies. Injury of the cervical spine is so frequently associated with a combined injury of the head and shoulder that special attention should be given to the cervical spine when the unconscious patient has also sustained a fractured clavicle or injury to the shoulder girdle. We have seen a considerable number of cases in which there was a combination of head, cervical spine and shoulder injury.

Cord lesions from fracture-dislocation are rarely progressive. Experience shows that the maximum damage to the cord is usually manifested immediately, and, if the cord has not been crushed, considerable recovery extending over a long period may be expected. It is highly probable that the inherent tendency of the partial lesion to recover much of the function temporarily lost deserves the larger share of the credit for improvement following operation or manipulative procedures which decompress the spinal canal or restore vertebral alignment. It is difficult to evaluate the effect of operation in incomplete lesions, but certainly there is good reason to believe that the improvement in many cases due to the processes of repair has been erroneously attributed to laminectomy.

When we first applied the Queckenstedt test in 1923 for the determination of compression of the cord in cases in which there was complete paralysis, it was hoped that prompt relief of pressure would restore some function of the cord, and for a number of years laminectomy was done in all cases if the patient's condition permitted. The results have shown the operation to be futile in these cases for the reason that the damage is maximal at the time of impact and restoration of function is therefore impossible.

No satisfactory explanation can be offered here for the reported recovery after laminectomy of the occasional patient who is said to have immediately lost all cord function below the level of injury, but it may be suggested that an accurate history probably could not be obtained in these cases or that the neurologic examination was incomplete. It may also be that the criteria of a complete cord lesion as recognized by some writers might have been classified as incomplete by others. We have regarded an early positive Babinski reflex in the absence of any other signs of cord function distal to the lesion, as evidence that the lesion is not complete.

Herniation of the intervertebral disk into the spinal canal caused by fracture has been found in our series of injuries to the spinal cord. If the resulting cord lesion is instantly complete from the impact of the dislocated disk, it would seem that the prognosis would be practically the same as that of a complete lesion

from fracture-dislocation in which the cord was crushed by displaced bone. The absence of x-ray evidence of deformity of the spinal column in severe injuries to the cord does not necessarily mean that a posterior dislocation of the cartilage has injured the cord. Vertebral recoil following extensive dislocation may have taken place, giving a practically normal roentgenogram, but the cord lesion may nevertheless be permanent.

#### USE OF SKELETAL TRACTION

Skeletal traction for the treatment of cervical fracture-dislocation suggested itself to one of us (C. C. C.) in June 1932 as a procedure of necessity in a case of telescoping fracture-dislocation of the axis on the third cervical vertebra without injury to the cord. Ordinary halter traction, so unsatisfactory as a method of cervical extension, could not be employed in this case because of an associated compound fracture of the skull and a compound comminuted fracture of the mandible. After weighing carefully the importance of reducing the exaggerated dislocation and the impossibility of applying traction by the methods then in use, we decided that the circumstances in the case required the application of extension tongs to the skull for the reduction of the dislocation. Edmonton tongs were applied to the skull in this case by our associate Dr. W. G. Crutchfield. It was obvious from the beginning that this type of traction was far more comfortable than that which we were accustomed to apply. X-ray examination showed widening of the intervertebral spaces and partial reduction of the dislocation by the skeletal traction. Functionally the results were excellent.

The principle of skeletal traction having been established, a most ingenious apparatus for the application of this type of traction in cervical injuries was devised by Dr. Crutchfield, and this apparatus carries out in a simple and more effective manner all the principles of the original conception. The technic of application and the results to be expected from skeletal traction by skull tongs have been discussed by Dr. Crutchfield<sup>4</sup> in a series of papers.

We have substituted skeletal traction for laminectomy in cases of complete cervical injuries with dislocation. We have seen no improvement in the function of the cord from the use of skeletal traction in these cases, and in this respect it has achieved no more than laminectomy. Skeletal traction, however, is a very minor procedure and carries practically no risk. It will reduce the dislocation and relieve the root pains, which may be very troublesome in some cases. It has therefore been used in complete lesions for the reduction of dislocation and relief of root pains and as a compromise between the futility of laminectomy and the policy of complete inaction, which is so unsatisfactory to the patient and his relatives.

#### INCOMPLETE LESIONS

The treatment of incomplete lesions of the cord offers a field for useful surgery provided there is pressure on the cord. Incomplete lesions of the cervical region with fracture-dislocation may be treated by skeletal traction for from eighteen to twenty-four hours. After this time, if the cord lesion is stationary or increasing and the block continues, laminectomy is indicated. In cases of cervical dislocation with mild

4. Crutchfield, W. G.: Skeletal Traction for Dislocation of the Cervical Spine, *South. Surgeon* 11:156-159 (June) 1933; Fracture-Dislocations of the Cervical Spine, *Am. J. Surg.* 38:592-598 (Dec.) 1937.

or no injury to the cord, reduction of the dislocation by skeletal traction is the ideal treatment. Recurrence of the dislocation may be prevented by appropriate orthopedic measures.

A subarachnoid block caused by cervical fracture-dislocation, in our experience, is not usually removed even though the dislocation is completely reduced by skeletal traction. With regard to incomplete cord injuries of the dorsal or upper lumbar region, we are not prepared to express an opinion as to the effect of hyperextension on a subarachnoid block, since we prefer laminectomy as a primary procedure in such cases. It should be said, however, that a review of the literature indicates that hyperextension in the treatment of compression fractures of the dorsal and lumbar regions with associated injury of the cord or cauda equina is often satisfactory. It appears that hyperextension in some hands has superseded laminectomy in the treatment of these cases.

Restoration of the alinement of the vertebral column at any level may leave a contused swollen cord compressed and incarcerated by the dura. The continuing block after reduction of the dislocation may be demonstrated by the Queckenstedt test. In such a situation there would not be complete relief of circulatory impairment in the contused cord segments, and as a result an incomplete lesion might become progressive. If symptoms of impairment of the cord are not ameliorated by reduction of the dislocation, or if the symptoms should increase and the block continue, indications for laminectomy are as urgent as if there had been no reduction of the dislocation.

The fear of producing further injury to the cord by manual reduction of a cervical dislocation in partial injuries is well founded, and it is difficult also to free one's mind of considerable apprehension for the fate of the cord when compression fracture-dislocations of the dorsal and upper lumbar regions with incomplete cord injury are reduced by hyperextension. If the dorsal canal has been narrowed by the injury and particularly if there is a fracture of the laminae or pedicles, further encroachment on the canal, however slight, from manipulation of the vertebral segments, might result in an increase of paralysis or even a total loss of cord function. The withholding of an anesthetic during the manipulation incident to manual reduction of cervical dislocations or hyperextension of the dorsal and lumbar lesions is of little protection against further injury to the cord. Should pressure on the cord be suddenly increased by the manipulation, the damage is instantaneous, just as in the case of complete lesions from fracture dislocation in which the crushing of the cord is coincident with the impact of the dislocating vertebra. The gradual unlocking of a cervical dislocation by skeletal traction is not attended by the risk of further injury to the cord. In this respect it is in marked contrast to manual reduction of cervical dislocations and hyperextension procedures for the relief of dorsolumbar lesions.

It is of some importance to determine the proper sequence of the steps in the treatment of incomplete dorsal injuries, associated with compression fractures. It would be most helpful to know whether a severe incomplete lesion with pressure on the cord can be more safely managed first by hyperextension and then by laminectomy if the compression is not relieved, or whether the order of these procedures should be

reversed. Because of the limitation of x-ray studies in disclosing the position of the fragments of bone and their possible encroachment on the dura, it must be assumed that evidence of complete block associated with fracture-dislocation is an indication that further encroachment on the cord may result in increased damage to this important structure. For this reason it would seem safer in these cases to perform a laminectomy to give greater protection to the cord before hyperextension is attempted. There should be little hesitation in using hyperextension for reduction of deformity in immediately complete lesions of the dorsal cord. The correction of deformities due to compression fracture and dislocation, particularly in the lower dorsal and lumbar regions, is highly desirable even with irreparable cord lesions because of the longer duration of life and the wider range of activities which these patients may have, as contrasted with complete lesions of the upper dorsal and cervical regions. It is true that the reduction of a dislocation above the cauda equina cannot be expected to bring about improvement in those cases in which the lesion shows immediate and complete loss of cord function, but hyperextension may restore the column to normal alinement and prevent root pains.

Laminectomy for injuries involving the cauda equina is not restricted by the limitations which experience has imposed in the treatment of lesions of the cervical and dorsal cord. The cord, being a solid cylindric structure, is more vulnerable to a compressing force than the bundle of roots which comprise the cauda equina. Moreover, the cauda equina has a greater capacity for resisting the effects of injury, and the motor roots possess the power of regeneration under favorable conditions even after severe injury or complete division. The relief of compression, while not benefiting the sensory roots already destroyed, may protect others not so badly damaged from progressive injury due to pressure of a deformed column. Laminectomy is therefore indicated in fracture-dislocation of the lumbar spine involving the cauda equina, even when a complete nervous lesion appears to have been immediately produced. Delay in operating on lesions of the cauda equina is likely to add to the damaging compression complications due to formation of adhesions, making an adequate operation extremely difficult or even impossible.

The technic of laminectomy for injuries to the cord may be briefly considered. The greatest care is necessary in handling the patient and transferring him to the operating table to avoid further injury to the cord. Local anesthesia is generally satisfactory and is preferred, especially in cervical operations. In injuries high on the cervical spine the use of morphine should be avoided. Before the operation the fluid below the compression is removed by lumbar puncture and replaced by air. The disclosure of the subarachnoid air after the dura is opened promptly indicates that the lower level of the compression has been relieved, while the free escape of fluid from above shows that the highest level of the compression has been removed. In fracture of the laminae the greatest care is necessary in separating the attachment of the muscles and in removing the bone to avoid further damage to the cord. Wide separation of the muscles from each side is generally unnecessary and should be avoided whenever possible. Hemorrhage from the muscles is controlled

entirely by the electrocautery, and in no operation is this equipment more useful. The level of the greatest bone compression is usually determined by x-ray study before operation and verified by the appearance of the column after operative exposure. The laminae adjacent to those of the displaced vertebrae are first removed and the arch compressing the cord is reserved for removal last, as an added protection to the underlying cord. Incision of the dura should begin above or below the level of compression and continue until the constriction of the cord is entirely relieved. In some cases of pressure by fragments of laminae it is unnecessary to open the dura. If opened, however, and this is usually required in confusion of the cord, no effort is made to suture the dura. In some cases traction combined with simultaneous pressure over the displaced vertebra in the proper direction may restore alignment during the laminectomy. Drainage is rarely required.

After cervical laminectomy, the head, neck and upper part of the chest should be immobilized by a plaster shell extending from the occiput to the lower lumbar region. The advisability of fixation in hyperextension after laminectomy for dorsal and lumbar injuries should be determined in consultation with the orthopedist.

#### MANAGEMENT OF SEVERE INJURIES

The general management of patients with severe cord injuries is obviously of the greatest importance. Pressure sores may be prevented by careful nursing and the use of cork or air mattresses. The complication of bedsores and infection seriously retards the progress of an incomplete lesion, delays or prevents the advent of an automatic bladder in the complete lesions and adds enormously to the problems of nursing care and expense of treatment. In our series of cases various methods of management of the paralyzed bladder have been tried. Intermittent catheterization, the use of a retention catheter, allowing the bladder to overflow, and suprapubic cystostomy have all been given a fair trial. The value and disadvantages of all these methods have been carefully considered, and we have adopted suprapubic cystostomy with drainage as a routine measure for all male patients with paralysis of the bladder due to an injury to the cord. This method has seemed to give the patient a greater protection from infection of the bladder and kidneys, and at the same time it has simplified the general nursing care of the patient. A retention catheter is nearly always followed by some form of genito-urinary infection in the male, but it is entirely satisfactory in the paralyzed female patient.

In our clinics all patients with a spinal injury are admitted primarily to the neurosurgical service. If the patient has a cord injury, a careful neurologic examination together with adequate x-ray study and the Queckenstedt test is promptly made to determine whether laminectomy is required. It may be necessary to repeat the Queckenstedt test several times before a decision can be made as to whether operation is indicated. Cases showing no involvement of the cord are transferred to the orthopedic service. All hyperextension procedures for injuries with or without associated impairment of the cord are conducted by the orthopedic department. Our urologic and orthopedic colleagues have generously cooperated in the management of these cases.

In a series of 259 consecutive patients admitted to one of our clinics (Medical College of Virginia) in a five year period ended Jan. 1, 1938, during which

time skeletal traction for cervical dislocation was originated, there was a group of eighty patients with cord lesions or root injuries involving important peripheral nerves. The location of these lesions was as follows: fifty-three cervical, fourteen thoracic and thirteen lumbar. There were thirty-one patients with complete cord lesions, twenty-four of whom died in the hospital. There was no improvement in the function of the cord in any of these cases. There were forty-nine incomplete cord lesions with twelve hospital deaths. Associated injuries rather than the cord lesion were responsible for death in a number of the latter cases. The incidence of associated injuries was high (twenty-four cases).

Laminectomy was performed in ten of the eighty cases analyzed in this paper. There were five laminectomies in the cervical region and five below this level. Of the cervical laminectomies, four were fatal or unimproved. The case in which there was improvement was incomplete and presented a subarachnoid block as the indication for laminectomy. Of the five patients who had laminectomies performed for dorsal or lumbar injuries or both, three were improved, one was unimproved and one died of urinary sepsis. Skeletal traction was employed in twenty-four cases of the group presenting cervical dislocation associated with injury to the cord or severe root involvement, and sixteen of these patients died or were unimproved while eight patients showed improvement. In the series, twenty-one patients were treated by orthopedic measures alone.

Statistics on injuries to the cord associated with fracture-dislocation are of little value as a guide to treatment, but a study of the group of eighty cases analyzed in the preparation of this paper corroborates fully an impression we have held for some years, while dealing with a much larger number of cord injuries, that surgery has a limited application in the treatment of such lesions.

#### SUMMARY

1. Laminectomy for injury to the spinal cord due to fracture-dislocation is indicated only for the relief of localized compression of the cord which has not been destroyed at the level of the injury.

2. Compression of the cord can be determined accurately only by the Queckenstedt test. If the test is negative there is no indication for operation in closed injuries, regardless of the severity of the lesion. If the test is positive, laminectomy is indicated only if one believes that the cord possesses some capacity for recovery.

3. Lesions of the cord producing immediate and complete physiologic interruption have, in our experience, shown no indication of recovery regardless of the treatment employed. We have come to regard operation in these cases as a futile procedure.

4. Reduction of the dislocation in the cervical region by skeletal traction, while not improving the patient's chances for restoration of cord function in complete cord lesions, is in such cases useful for the relief of root pains. It is a practical and simple substitute for laminectomy.

5. Severe incomplete cervical cord lesions showing compression with stationary or increasing symptoms may be treated for from eighteen to twenty-four hours by traction. If the symptoms are unchanged and pressure persists after this time, laminectomy under local anesthesia is indicated while traction is being maintained.

6. Severe incomplete lesions of the dorsal region with a block require laminectomy. If there is a compression fracture or fracture-dislocation with a block, laminectomy should precede hyperextension.

7. Prompt laminectomy is indicated in complete lesions of the cauda equina with compression caused by fracture-dislocation.

### ABSTRACT OF DISCUSSION

DR. FREDERIC C. BOST, San Francisco: It is indeed a privilege to hear from any one who has had as many as 250 cases of spinal injury in a five year period. I think you will all agree with me that such an experience ought to be worth a great deal to all of us. I know of no more serious injury that confronts me as an orthopedist than cervical spine injuries. As soon as one sees a patient with a fracture dislocation of the cervical spine or other portion of the spine, particularly with complete cord injury, one is confronted with a lot of questions. Dr. Coleman and Dr. Meredith in their paper have answered all these questions. It is brought out clearly that the Queckenstedt test, a careful history of the period immediately following injury and a thorough neurologic examination will allow it to be determined whether or not laminectomy is indicated. In the other cases one may resort to skeletal traction. Skeletal traction may be used with the Crutchfield tongs or by any other method which one may desire. One may hope to reduce the fracture-dislocations of the cervical spine without running the danger of doing further damage to the already injured cord. The authors have also brought out clearly the pathologic changes that follow cord injury, and when one realizes what these are one will know that laminectomy can offer but little in a complete cord lesion. We, therefore, as surgeons may follow a policy of nonsurgical intervention rather than subjecting the patient to something that may do him no good. A careful perusal of this paper will show that the principles which it enunciates will allow us to establish a nice regimen on which these patients can be handled.

DR. C. C. COLEMAN, Richmond, Va.: I thank Dr. Bost for his discussion. I should like to correct the erroneous impression he received from my paper as to the number of cases. It is true that we have had 259 cases of spinal injuries in one group of hospitals (Medical College of Virginia) in a five year period, but not 250 cervical injuries as he evidently understood us to say. I am quite sure that he will find the statement in the original paper as to the number of cord injuries as well as the number of spinal injuries in which the cord was not involved.

**The Insulin Molecule.**—Another hormone which evidently has its origin in the amino acids of the blood is insulin. In contrast to thyroglobulin, which yields thyroxine, insulin appears to contain no prosthetic group to which its physiological action may be attributed. Intensive investigations designed to disclose the presence of some peculiar constituent of unusual potency have merely served to emphasize the typical protein nature of the substance. From hydrolysates of the crystalline compound nine amino acids have been separated and identified. These are cystine, tyrosine, glutamic acid, leucine, arginine, histidine, lysine, phenylalanine and proline. Although the above are among the most commonplace components of ordinary proteins, they are said to account for practically the entire insulin molecule. The unique properties of the hormone evidently are due to the structural arrangement of its constituents. In this connection it is of interest to note that many enzymes, particularly those which effect hydrolytic changes, appear to be simple proteins and that their activity is to be ascribed to peculiarities in the disposal of the amino acids within the molecules rather than to the presence of prosthetic groups. According to Northrop, "the formation of enzymes is a special case of the more general problem of the synthesis of proteins."—Rose, William C.: *The Physiology of Amino Acid Metabolism*, *Proc. Inst. Med. Chicago* 12:98 (April 15) 1938.

## SULFANILAMIDE IN THE TREATMENT OF 106 PATIENTS WITH MENINGOCOCCIC INFECTIONS

JULIUS M. WAGHELSTEIN, M.D.

BALTIMORE

The observation of Buttle and his associates<sup>1</sup> that sulfanilamide protected and cured mice of an experimentally induced meningococcic septicemia<sup>2</sup> has been amply confirmed by Proom,<sup>3</sup> Rosenthal and his associates,<sup>4</sup> Levaditi and Vaisman<sup>4</sup> and Brown.<sup>5</sup> Branham and Rosenthal<sup>6</sup> and Brown<sup>5</sup> concluded as a result of their observations on experimental meningococcic infections in mice that a combination of sulfanilamide with an effective antimeningococcus serum produced a greater protective or therapeutic effect than either of the agents by itself. Schwentker, Gelman and Long<sup>6</sup> in a preliminary report considered sulfanilamide to be as effective in the treatment of meningococcic infections in human beings as good specific antisera. All of their eleven patients with but one exception were treated by both the parenteral and the intrathecal route. In this group of eleven patients there was but one death.

Since this report was published, McIntosh and his co-workers,<sup>7</sup> Mitchell and Trachsler,<sup>8</sup> Bernstein,<sup>9</sup> Carey,<sup>10</sup> Basman and Perley<sup>11</sup> and Brennemann<sup>12</sup> have reported that patients ill with meningococcic infections and treated with sulfanilamide have made definite recoveries from their disease. Pongratz<sup>13</sup> has reported recoveries in three patients suffering from meningococcic meningitis who were treated with prontosil<sup>14</sup> parenterally and perorally and with serum by the intrathecal route.

Willien<sup>15</sup> treated five patients ill with meningococcic infection with sulfanilamide. He states that "the clinical response of the patients to treatment with sulfanilamide was satisfactory in every case" and that a favorable outcome was achieved "even with oral administration alone."

Recently Eldahl<sup>16</sup> has reported on the therapeutic use of sulfanilamide in twelve patients suffering from severe forms of meningococcic meningitis. Nine of these patients recovered. All twelve patients were treated by the intramuscular and intrathecal routes. In this paper Eldahl reaches the conclusion that sulfanilamide "has but little effect if the remedy is administered exclusively by mouth or intramuscularly." This statement is in contradiction to the observations of

Marshall and his associates<sup>17</sup> and to those of Long<sup>18</sup> that sulfanilamide easily passes through the normal and inflamed meninges in about the same concentration as is found in the blood.

The present report is complementary to the original communication of Schwentker, Gelman and Long and in it will be discussed the therapeutic results obtained in seventy-two patients ill with meningococcic infections and treated with sulfanilamide alone, and the effects of combined antimeningococcus serum and sulfanilamide therapy in the treatment of thirty-four additional patients suffering from meningococcic infection.

Since the advent of sulfanilamide, 106 patients have received this drug during the treatment of meningococcic infections. For subcutaneous and intrathecal administration, a 1 per cent solution of the powdered sulfanilamide in physiologic solution of sodium chloride

TABLE 1.—*Age Incidence of Patients Treated with Sulfanilamide*

Age, Years.....	0-2	2-5	5-10	10-20	20-30	30-40	40-50	50-60
No. of patients...	12	19	18	22	20	8	3	4

is used. The solution is given intraspinally in amounts 5 cc. less than the quantity of the spinal fluid withdrawn. When given by hypodermoclysis the calculated daily dosage is administered in two divided doses at intervals of twelve hours. Hypodermoclysis is continued twice a day until the patient is able to tolerate sulfanilamide by mouth. I favor the oral administration of sulfanilamide. The drug is given in this manner unless persistent vomiting is present. In comatose patients the tablets are dissolved in water and given by nasal catheter every four hours. In the combined method of therapy serum is injected intraspinally and the same dosage of sulfanilamide given either by mouth or by hypodermoclysis. A minimum of serum is administered in an attempt to reduce the number and severity of serum reactions. I have found that only two intraspinal injections of serum are necessary in the treatment of meningitis and that usually after the first lumbar puncture the spinal fluid is sterile. At the beginning of either method of treatment with sulfanilamide a large initial dose, usually equal to the calculated daily dose, is given either by mouth or by hypodermoclysis.

The first step in the treatment of meningococcic meningitis is lumbar puncture. If the spinal fluid is cloudy and petechiae are found on examination, the treatment of meningococcic meningitis is immediately instituted. If, on the other hand, the diagnosis is doubtful a direct smear of the spinal fluid is first examined and, if gram-negative diplococci are found, the treatment is begun. Serum or sulfanilamide is given intraspinally by the gravity method. Before serum is injected, a sensitivity test to horse serum is done. In the last few cases treated with the combined method, one ampule containing 15 cc. of antimeningococcus serum was injected after drainage of the subarachnoid space. If sulfanilamide alone is used, 5 cc. less than the amount of spinal fluid withdrawn is injected intrathecally. Immediately after the first lumbar puncture, the large initial dose of sulfanilamide is offered. If, for any reason, the patient cannot take the sulfanilamide by mouth, the drug is given by nasal catheter. Only when the patient vomits is the sulfanilamide

given by hypodermoclysis. Hypodermoclysis should be repeated at intervals of not more than twelve hours. The sulfanilamide medication is continued for one week. From twelve to twenty-four hours after the first lumbar puncture a second is done, at which time sulfanilamide or serum is again injected into the subarachnoid space.

I have used the same dosage of sulfanilamide in the combined method as I have in cases in which sulfanilamide alone was given. The daily dose of between 5 and 6 Gm. is rarely exceeded in adults. In infants the dosage is calculated on the basis of 250 mg. per kilogram of body weight daily. In older children the dosage is approximately 1 Gm. to 20 pounds (9 Kg.) of body weight. During the administration of sulfanilamide, fluids are restricted. In adults liquids are limited to between 1,200 and 1,500 cc. a day. The limitation of fluids, I believe, is important in maintaining a therapeutic level of sulfanilamide in the blood and spinal fluid. The state of hydration of the patient is important in determining the extent to which fluids should be limited. In addition, sodium bicarbonate is always given in the same dosage as the sulfanilamide. Acidosis is apt to occur during administration of sulfanilamide, and it is to combat acidosis that sodium bicarbonate is given. Acidosis is especially prone to occur in infants and young children, and it is in this group that the giving of sodium bicarbonate is doubly important.

Among the total number of patients treated with sulfanilamide there were nineteen deaths, a percentage of 18. Seven of the deaths occurred within twenty-four hours. Among the adequately treated patients there were twelve deaths, a case fatality rate of 12 per cent. This figure may be contrasted with a total fatality rate of 27 per cent among 368 patients treated with serum in 1935 and 1936. If the patients who died within twenty-four hours are discounted, 17 per cent of the adequately treated patients who received serum died.

TABLE 2.—*Summary of Results*

Number of Cases	Type of Treatment	Total Deaths		Twenty-Four Hour Deaths		Deaths in Adequately Treated Cases	
		Number	Per Cent	Number	Per Cent	Number	Per Cent
72	Sulfanilamide alone	11	15.27	3	4.16	8	11.59
34	Combined sulfanilamide and serum	8	23.52	4	11.76	4	13.33
106	Sulfanilamide alone and combined sulfanilamide and serum	19	17.92	7	6.6	12	12.12
368	Serum	69	26.9	45	12.12	54	16.71

Sulfanilamide alone was used in seventy-two cases with eleven deaths, a case fatality rate of 15 per cent. There were three deaths occurring within twenty-four hours after hospitalization. When the deaths which occurred within twenty-four hours are deducted, there remain eight patients who died after receiving adequate treatment, or 12 per cent.

The combined method of treatment was instituted in thirty-four cases with eight deaths, a case fatality rate of 24 per cent. In this group there were four deaths which occurred within twenty-four hours, leaving a total of thirty adequately treated cases with four deaths, a fatality rate of 13 per cent. When this

17. Marshall, E. K., Jr.; Emerson, Kendall, Jr., and Cutting, W. C.: *J. Pharmacol. & Exper. Therap.* 61: 196 (Oct.) 1937.  
18. Long, P. H.: Unpublished observations.

method of treatment was first used in Sydenham Hospital, eight patients were treated with four deaths. This method was then discontinued for several months, and since it has been resumed twenty-six cases have been treated with the occurrence of three deaths, two of which occurred within twenty-four hours.

In the group in which the combined method was used there were thirty-two cases in which more than one lumbar puncture was performed. Of this number there was only one case in which more than one positive spinal fluid culture was obtained. At least two lumbar punctures were done on sixty-six of the patients treated with sulfanilamide alone and from eighteen of this number more than one positive spinal fluid culture was obtained. Sixteen of this number had received sulfanilamide by hypodermoclysis throughout or at least for forty-eight hours at the beginning of the treatment. Only two of the eighteen patients had received the drug by mouth. Of those patients receiving sulfanilamide alone, forty-six had been given the drug by hypodermoclysis for at least forty-eight hours at the beginning of treatment and twenty-six were given the drug by mouth. In the group in which the drug was given subcutaneously there were nine deaths, and of those taking sulfanilamide by mouth there were only two. This would seem to indicate that giving the drug by mouth or nasal catheter every four hours was superior to the subcutaneous method of administration every twelve hours.

The concentration of sulfanilamide in the blood and spinal fluid is subject to wide variation when given by hypodermoclysis every twelve hours. At the end of the twelve hour period the sulfanilamide will usually be at a very low level, depending on the urinary output. On the other hand, in cases in which sulfanilamide is given by mouth or nasal catheter every four hours the concentration will tend to be fairly constant at what is thought to be a reasonable therapeutic level.

An attempt has been made to reduce the number of lumbar punctures in the treatment of meningitis. It was found, as already mentioned, that in very few cases was more than one positive spinal fluid culture obtained. I have noted that of all the cases in which sulfanilamide was given by mouth or by gavage every four hours, in only three were there more than one positive spinal fluid culture. Using this factor as a guide, I reduced the number of lumbar punctures, and at present only two are performed. On fifteen patients only three therapeutic lumbar punctures were performed and on fourteen only two were done. Not only does this reduce very markedly the discomfort suffered by the patient in the treatment of meningococcic meningitis but it is also very helpful from the standpoint of the time saved by the hospital attendants. The clinical course of the patient is not altered by the reduction of the lumbar punctures.

Of the total number of patients treated with sulfanilamide, blood cultures were obtained from ninety-four. Thirty-one, or 33 per cent, of this number were positive for the meningococcus. Eighteen blood cultures were obtained from the nineteen patients who died. Ten of the blood cultures obtained were found to be positive for the meningococcus, a percentage of 56.

The complications due to sulfanilamide therapy were relatively mild and infrequent in occurrence. There were three cases of hemolytic anemia and these were treated simply by stopping the drug and forcing fluids. Hemolytic anemia occurred from five days to one week

after sulfanilamide medication was begun and the drug could be discontinued at that time with very little fear of the recurrence of meningococcic infection. There were two cases of sulfanilamide rash, one of which preceded the onset of the hemolytic anemia by twenty-four hours. These cases also occurred at the end of a week, at which time sulfanilamide was usually discontinued. The complications associated with meningococcic infections occurred just as frequently as in the cases in which serum therapy was used. In 368 cases in which serum therapy was used there were ten cases complicated by arthritis and two by endophthalmitis. Among the patients treated with sulfanilamide arthritis developed in five, and endophthalmitis developed in a child who had had a severe injury to the eye two weeks before there had been clinical evidence of the meningococcic infection. There were five cases of deafness occurring in the sulfanilamide treated group and only six in the 368 patients treated with serum. Of the five cases of deafness, in two the deafness was present at the time of admission before treatment was started.

There has been a reduction in the number of recurrences since the introduction of sulfanilamide in the treatment of meningococcic infections. There was only one recurrence in the 106 cases here reported, and in this case sulfanilamide per se was not given but one of the derivatives. On readmission this patient did very well when treated with sulfanilamide alone and recovered very rapidly. Of the 368 serum treated patients there were six recurrences.

#### RESULTS

1. There were 106 patients with meningococcic infection treated at Sydenham Hospital with nineteen deaths, a fatality rate of 18 per cent. The case fatality rate in the adequately treated group was 12 per cent.

2. When sulfanilamide alone was used the fatality rate was 15 per cent. In the adequately treated cases, the fatality rate was 12 per cent.

3. The combined method of treatment was used in thirty-four cases with a case fatality rate of 24 per cent. The fatality rate in the adequately treated group was 13 per cent. Among the last twenty-six patients treated in this manner there were three deaths, two of which occurred within twenty-four hours.

4. The spinal fluid cultures were more consistently sterile after from twelve to twenty-four hours of treatment in those cases in which sulfanilamide was taken every four hours by mouth or by nasal catheter rather than when given every twelve hours by hypodermoclysis.

5. The number of lumbar punctures in the treatment of meningitis has been markedly reduced.

6. The complications due to sulfanilamide therapy were infrequent and very mild. The number of recurrences were reduced. Those complications due to meningococcic infections were not significantly reduced in occurrence.

#### CONCLUSION

Since the introduction of sulfanilamide in the treatment of meningococcic infection there has been a definite decrease in the number of deaths, not only in the adequately treated but also in those fulminating cases which usually terminate fatally within twenty-four hours. The discomfort suffered by the patient directly due to the treatment is lessened owing to the simplification of the treatment, and the hospital stay has been notably reduced.

COMBINATION COURSES OF BISMUTH  
ADMINISTRATION

TORALD SOLLMANN, M.D.  
H. N. COLE, M.D.  
AND  
KATHARINE HENDERSON, A.B.

WITH THE COLLABORATION OF GARRETT COOPER, M.D., WALTER  
SCHWARTZ, M.D., AND W. R. LOVE, M.D.

CLEVELAND

Intramuscular bismuth therapy against syphilis ranges from the extreme of very slow absorption from the oil suspensions of compounds that dissolve very slowly in water, such as the subsalicylate, and the other extreme of the relatively rapid absorption from watery solutions. With the watery solutions an effective concentration of bismuth in the blood and tissues is reached

cytate suspensions, adjusted to build up an effective concentration rapidly by use of the watery solution and a continuous concentration meanwhile by use of the salicylate suspension, the injections of the watery solution being graded off as the salicylate concentration rises. The course as projected consisted of ten weekly injections of an oil suspension of bismuth subsalicylate supplemented at the beginning by six injections of a soluble compound, three in the first week, two in the second week, one in the third week and none thereafter.

In one series the subsalicylate was given in the usual weekly dose: 1 cc. of a suspension in olive oil, which contained 0.13 Gm. of bismuth subsalicylate, or 75 mg. of bismuth. In another series double this dose, 2 cc., 0.26 Gm. of bismuth subsalicylate, or 150 mg. of bismuth, was employed. For the water-soluble compounds we chose iodobismitol and sobisminol, because their absorption rate is rapid while their excretion is less

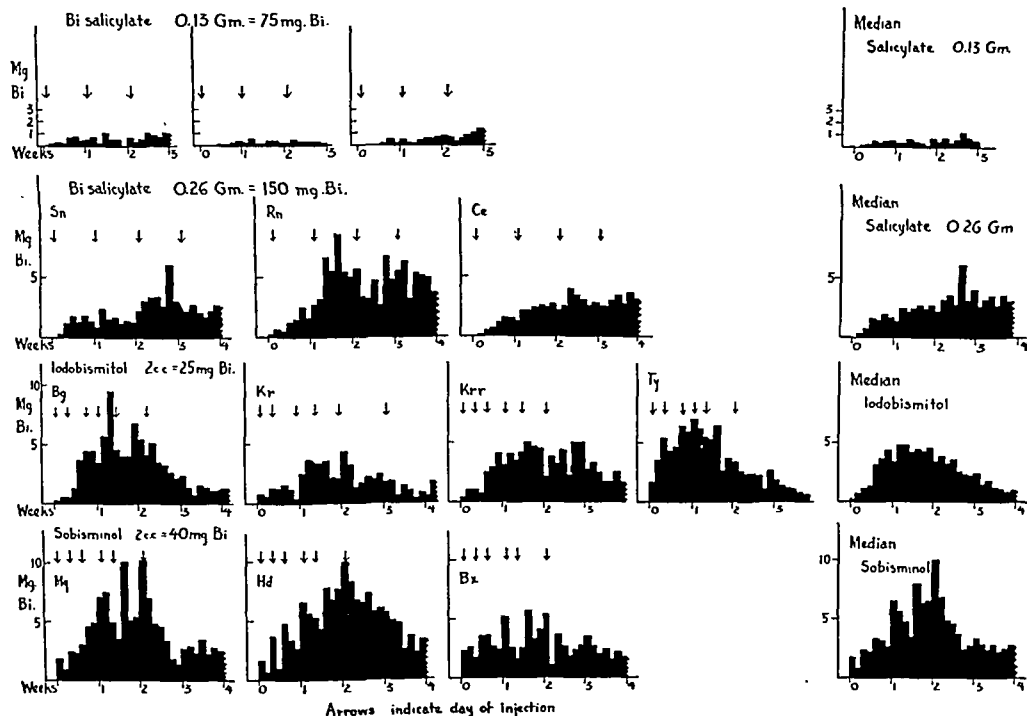

Chart 1.—Daily urinary excretion after injections of (a) bismuth subsalicylate 0.13 Gm., (b) bismuth subsalicylate 0.26 Gm., (c) iodobismitol 2 cc. per injection and (d) sobisminol 2 cc. per injection.

in a short time, perhaps after a single injection. As the excretion of these solutions is also more rapid, their action is relatively brief and they must be administered more frequently. The oil suspensions have the advantage that they may be given at longer intervals. They tend to become cumulative when injected once a week. The effective concentration in the blood is therefore approached more slowly, probably only after from two to four weeks. These extremes are bridged by a variety of bismuth preparations, such as oil suspensions of more soluble compounds and the oil-soluble compounds. It occurred to us that it might be advantageous to approach the problem in a different way, namely by an interlocking sequence of watery solutions and sali-

fugacious than that of the bismuth thioglycollate. The iodobismitol is a solution of 6 per cent sodium iodo-bismuthite and 12 per cent sodium iodide in propylene glycol. The intramuscular dose is 2 cc., equivalent to approximately 25 mg. of bismuth. Sobisminol is a true solution of 3 per cent sodium bismuthate, 8 per cent tri-isopropanolamine and 50 per cent propylene glycol, the remainder being water. The dose used was 2 cc. per injection, 60 mg. of sodium bismuthate, or approximately 40 mg. of bismuth. This resulted in the following experimental courses (the doses being given in milligrams of bismuth for each injection):

1. Bismuth subsalicylate 0.13 Gm., 75 mg. of bismuth
2. Bismuth subsalicylate 0.26 Gm., 150 mg. of bismuth
3. Iodobismitol 2 cc., 25 mg. of bismuth
4. Iodobismitol 2 cc., 25 mg. of bismuth, plus bismuth subsalicylate 0.13 Gm., 75 mg. of bismuth
5. Iodobismitol 2 cc., 25 mg. of bismuth, plus bismuth subsalicylate 0.26 Gm., 150 mg. of bismuth
6. Sobisminol 2 cc., 40 mg. of bismuth

This work was supported by grants from the Council on Pharmacy and Chemistry of the American Medical Association.  
Read before the Section on Dermatology and Syphilology at the Eighty-Ninth Annual Session of the American Medical Association, San Francisco, June 16, 1938.  
From the Department of Pharmacology and the Department of Dermatology and Syphilology, Western Reserve University School of Medicine, and City and University hospitals.

7. Sobisminol 2 cc., 40 mg. of bismuth, plus bismuth subsalicylate 0.13 Gm., 75 mg. of bismuth

8. Sobisminol 2 cc., 40 mg. of bismuth, plus bismuth subsalicylate 0.26 Gm., 150 mg. of bismuth

Three or four patients were used for each course, with daily determination of the urinary excretion of bismuth. The curve for each patient is shown in charts 1, 2 and 3, as is the median for each group. For simplicity the median curves were smoothed and projected by extrapolation, for the determinations were not continued after four weeks because of the difficulty of longer hospitalization of patients.

#### IODOBISMITOL AND BISMUTH SUBSALICYLATE

The results are shown in chart 4. The upper set of curves shows (a) the slowly ascending curve when bismuth subsalicylate alone is injected and the dose is 0.13 Gm. (75 mg. of bismuth) weekly. The average

curve reaches a considerably higher level, 2 mg. by the end of the first week and probably 4 mg. in the sixth week. Adding this curve to the curve for iodobismitol (b), which is identical with that in the upper figure, gives the sum shown in the dotted curve, c. This curve ascends gradually to a maximum of 6 mg. at the end of the fourth week and then falls to unite with the salicylate curve at the end of the fifth week, with a level a little above 3 mg. The actual curve runs higher at first, reaching 10 mg. at the end of the second week, and then descends to join the theoretic curve at the sixth week.

#### SOBISMINOL AND BISMUTH SUBSALICYLATE

For sobisminol and bismuth subsalicylate the curves are shown in chart 5, the upper group being for the 0.13 Gm. dose of salicylate (75 mg. of bismuth) and

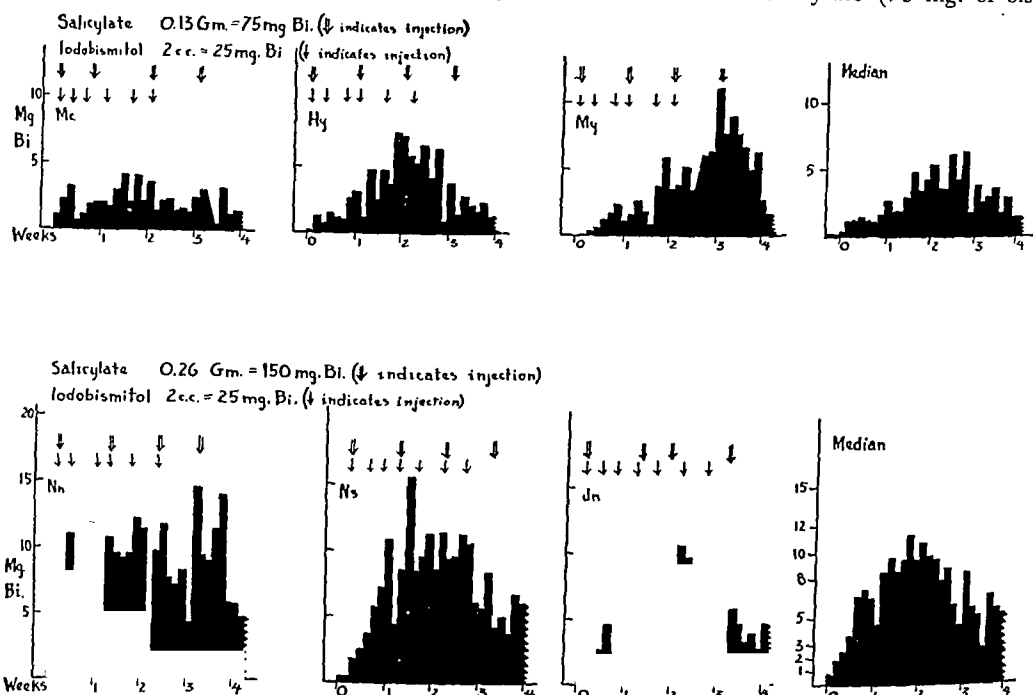

Chart 2.—Daily urinary excretion after injection of iodobismitol plus bismuth subsalicylate 0.13 Gm. and iodobismitol plus bismuth subsalicylate 0.26 Gm.

level of urinary excretion of 1 mg. of bismuth a day is reached in three weeks and 2 mg. of bismuth a day probably in six weeks. With iodobismitol alone (b) by a gradually descending sequence of doses, i. e. three the first week, two the second week, one the third week and none thereafter, the maximum of the excretion curve is reached in about ten days, at 4.5 mg. of bismuth a day. It would have fallen to the 2 mg. level about the end of the third week and below 1 mg. in the fourth week. The sum of the two curves would give the dotted curve (c), which is only slightly higher than the curve for iodobismitol alone for the first two weeks but then falls and keeps practically horizontal at about 2 mg. of bismuth a day until it fuses with the ascending salicylate curve at the seventh week. The actual excretion happens to ascend somewhat more slowly, but to about the same level (5 mg. of bismuth a day), after which its course is practically identical with the arithmetical sum.

The lower set of curves shows (a) the excretion after bismuth subsalicylate 0.26 Gm. (150 mg. of bis-

the lower group for the 0.26 Gm. dose (150 mg. of bismuth). The curves for the subsalicylate are the same as those in chart 4. The curve for sobisminol alone (b), in the descending doses which were used, reaches its maximum at a level of 7 mg. of bismuth about the end of the second week and descends gradually to about 2 mg. at the end of the fourth week and below 1 mg. at the sixth week. The sum of the two curves (c) is but little higher than that of sobisminol alone during the first two weeks, but the descent joins the ascending curve of the salicylate in the sixth week and thus remains above 2 mg. The actual curve for the combined medication (d) is practically identical with the theoretic curve.

When the curve for sobisminol is added to the curve for salicylate in the higher doses, as shown in the lower set of curves (c), the excretion reaches the maximum of 10 mg. of bismuth at the end of two weeks, falls to about 5 mg. by the end of the fourth week and keeps at this level until it joins the ascending curve there at about the end of the seventh week. The actual curve (d) runs somewhat higher.

The variation between the theoretic and the actual observations for the combination are probably not significant. The significant fact is that the combination attained a high excretion level in two weeks, which fell gradually to join the ascending salicylate curve in from five to seven weeks.

With the combination, therefore, the excretion from the very start is materially higher than that which is attained by salicylate alone after from five to seven weeks of administration; namely, 2 mg. of bismuth for the lower dose, 0.13 Gm. (75 mg. of bismuth), and 4 mg. for the higher dose, 0.26 Gm. (150 mg. of bismuth). During the initial two weeks, however, the excretion curve reaches a median of 5 mg. of bismuth with iodobismitol plus salicylate 0.13 Gm., from 6 to 10 mg. with iodobismitol plus salicylate 0.26 Gm., 9 mg. with sobisminol plus salicylate 0.13 Gm. and 12.5 mg.

insoluble bismuth salts, if they have been injected enough times, will reach a therapeutic level in the blood stream. If some combination can be added to this slowly rising bismuth curve that will raise the level within a day or so and hold it long enough so that it may gradually grade off into the rising level from the bismuth subsalicylate, the problem will be solved. This we believe we have achieved by the combined use of iodobismitol or sobisminol and weekly injections of bismuth subsalicylate. The accompanying table illustrates our point.

Such a form of bismuth therapy would be particularly useful in the acute stage of syphilis when the patient is sensitive to arsenic and it is necessary to rely on other antisyphilitic measures. Moreover, for the patient with early syphilis who is just starting therapy, this schema might be employed in the first course of

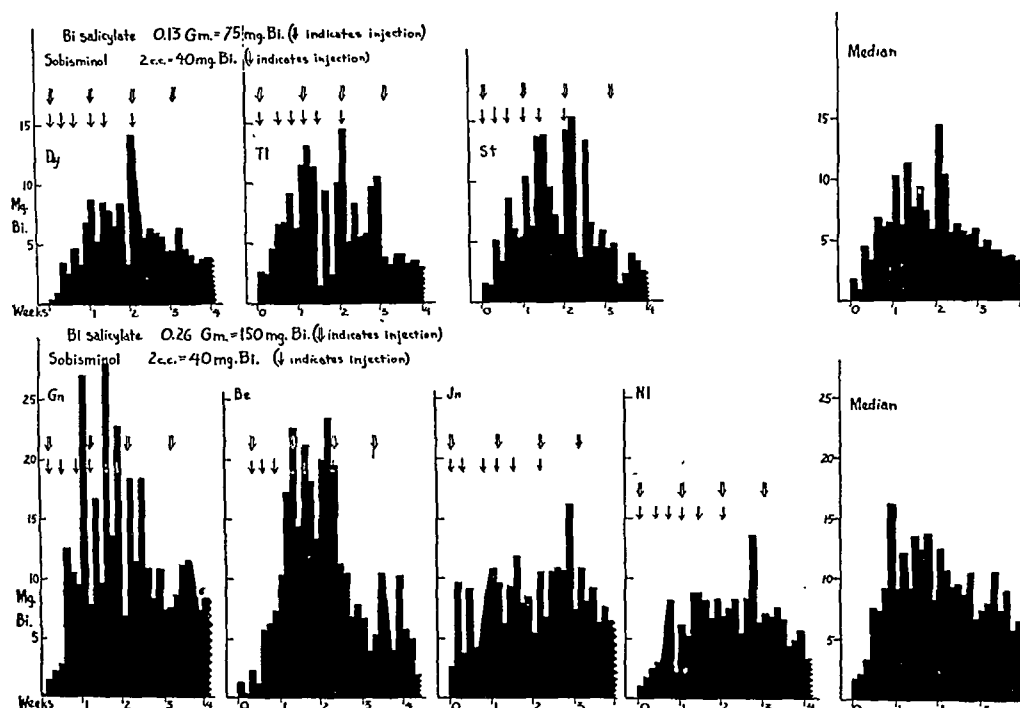

Chart 3.—Daily urinary excretion after injection of sobisminol plus bismuth subsalicylate 0.13 and sobisminol plus bismuth subsalicylate 0.26 Gm.

with sobisminol plus salicylate 0.26 Gm. It is reasonable to assume that this initial intensive medication should be useful for an intensive effect on the spirochetes, which would be maintained when the dose fell to the safer but still effective levels of the ascending salicylate curves. None of the patients showed any toxic effects, nor would these be expected, because the high concentrations are not continued for any length of time. We may add that the 0.26 Gm. dose of salicylate has been used in other cases for the whole course without toxic results.

#### CLINICAL COMMENT

One of the problems with bismuth therapy for syphilis is to achieve a rapid rise of the metal in the blood stream to a therapeutic level and to keep it there without too great hardship on the patient. This can be achieved by biweekly or triweekly intramuscular injections of certain water-soluble bismuth compounds, but what patient will consent to such frequent injection for ten or twelve weeks at a stretch, even if he can afford them? It is well known that eventually certain of the

bismuth therapy when the clinician is desirous of dealing a heavy blow to the spirochetes from another angle than that of arsenic. Again, it would be most useful for the patient who is sensitive to arsenic and has for

#### Schema of Combination Bismuth Treatment

example syphilitic meningitis. In certain cases the clinician would find the bismuth subsalicylate in 1 cc. doses (0.13 of bismuth) sufficient. Certainly for robust males this drug in 2 cc. doses could be employed. With this combined bismuth therapy the somewhat

more irritating injections of water-soluble bismuth preparations would gradually be supplanted by the comparatively painless medication with bismuth subsalicylate.

#### SUMMARY AND CONCLUSIONS

A graded sequence of injections of soluble bismuth preparations (iodobismutol and sobisminol) with continued weekly injections of bismuth salicylate produces a high initial concentration of bismuth as reflected in

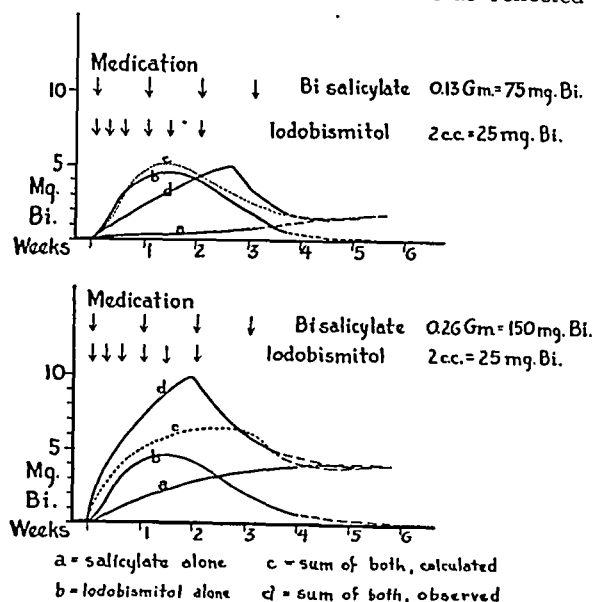

Chart 4.—Median curves for the urinary excretion of bismuth after injection of bismuth subsalicylate (a), iodobismutol (b) and bismuth subsalicylate plus iodobismutol (d). The presumptive further course is indicated by broken lines. The dotted lines (c) represent the arithmetical sum obtained by adding the two curves a and b. The upper set of curves gives results after salicylate 0.13 Gm. and the lower set after salicylate 0.25 Gm.

the urinary excretion, which reaches at the end of two weeks a level of from 4 to 12 mg. of bismuth a day, according to the drugs used. This concentration then falls so as to join the slowly ascending curve characteristic of salicylate injections about the end of from five to seven weeks, so that the median level does not fall below 2 mg. of bismuth for the lower dose (0.13 Gm.) of salicylate and 4 mg. of bismuth for the higher dose (0.26 Gm.) of salicylate. The sequence therefore secures the benefit of the intensive action of the water-soluble bismuth preparations in the early part of the course and the advantages of the convenience of salicylate injections in the latter part of the course.

This form of combined bismuth therapy is offered for use in the treatment of patients with acute syphilis who are sensitive to arsenic when a rapid but prolonged effect of bismuth is called for. It may also be profitably employed as the form of bismuth medication in the treatment of early syphilis.

#### ABSTRACT OF DISCUSSION

DR. GEORGE V. KULCHAR, San Francisco: The paper of Drs. Sollmann and Cole and their associates is a happy compromise, I think, between the two camps existing at present, those who advocate a soluble bismuth compound and those who believe an oil suspended bismuth to be more logical. I think the compromise evoked utilizes the best features of each. When it comes to bismuth, we are somewhat in a state of flux, perhaps induced by several questions. We do not know exactly what we desire therapeutically from a bismuth compound. In other words, is the spirocheticidal effect directly proportional to the absorbed dose, as it would seem from animal experi-

mentation, or should one take the other view, that the bismuth perhaps in combination with some protein acts as a catalyst or a spirochetostatic agent? The second question which leads to indecision is Does urinary excretion truly measure bismuth effect? In other words, is the number of milligrams of bismuth excreted daily in the urine a mathematical expression of the spirocheticidal effect? Another question which causes trouble along the same line is Can bismuth be accurately measured in the blood stream? The order of magnitude of bismuth determinations to a large degree makes the practicing syphilologist wonder whether it is an accurate index of absorption. If the concept is accepted that the spirocheticidal effect is directly proportional to the urinary excretion of bismuth, the method advocated by Dr. Cole and his associates affords rapid approach in the treatment of syphilis, particularly in the cases that they mentioned, and I might add in early syphilis in elderly patients to whom one hesitates sometimes to give an arsphenamine. So far as bismuth salicylate is concerned, this is one means of initiating treatment. The same effect may be obtained by the use of either one of the two soluble compounds mentioned by the authors, sobisminol and iodobismutol. The more rapidly absorbable and consequently excreted compounds seem to me to be more logical. Compounds of this type may be given over long periods of time without cumulative effects on toxicity.

Dr. P. J. HANZLIK, San Francisco: My colleagues at Stanford and Dr. J. R. Scholtz of Los Angeles have sufficient clinical data on bismuth salicylate to indicate that it is inefficient because it is an insoluble and poorly absorbed compound, and the authors' results also show that the absorption is very small. I believe I understand why a bismuth compound of that kind is chosen. It is retained for a long time in the body and assumed there is a continuous bismuth streaming through the tissues for sustained action on the syphilitic virus. But it may be questioned whether there is a continuous, or at least adequate, bismuth streaming through the tissues when one considers the poor absorbability of this product and the local tissue reaction to it. This product is walled off in the muscles and can be found at the injection site for weeks,

Chart 5.—Median curves for the urinary excretion of bismuth after injection of bismuth subsalicylate (a), sobisminol (b) and bismuth subsalicylate plus sobisminol (d). The presumptive further course is indicated by broken lines. The dotted lines (c) represent the arithmetical sum obtained by adding the two curves a and b. The upper set of curves gives results after salicylate 0.13 Gm. and the lower set after salicylate 0.26 Gm.

months and sometimes even years. Soluble compounds of bismuth are unquestionably superior to the insoluble. I agree with the authors that iodobismutol and sobisminol may be placed somewhere between the most soluble and the least soluble bismuth compounds and produce the desired result so far as the concentration of bismuth and action in the tissues are concerned. The time period for disappearance of the virus

from syphilitic lesions and their healing is inversely proportional to the dosage; in other words, the higher the dosage or the higher the concentration in the tissues, the faster are the clearing and healing of the lesion. The urinary excretion of bismuth is the simplest and most practical guide to the efficiency of medication, much as one would like to have more direct control of the bismuth content of tissues and blood. We have introduced a short clinical method for estimating bismuth in urine, which can be readily applied by an office, technical or clinical assistant. It provides a fairly good chemical control on the treatment. Since insoluble products are much less efficient and desirable, may I suggest the use of an oral bismuth compound, in an exclusive bismuth system, for more efficient and sustained effects and greater convenience? I don't know what the authors think about this, but the oral sobisminol is definitely effective in syphilis. I appreciate the objections to oral medication in the treatment of syphilitic patients, but, aside from the toxicity of arsenicals and mercurials, most of these are not valid and will disappear when there is a better appreciation of the possibilities for bismuth. As for toxicity and possible injuries to viscera, blood and other undesirable effects, sobisminol is not comparable with acetarsone or mercury, whether sobisminol is taken by the patient himself or given under the supervision of a physician.

DR. BEN A. NEWMAN, Los Angeles: It is well known that the most frequent untoward reaction and complaint, especially by patients in private practice, concerns the deposition of bismuth in the gum margins. Have the authors observed any increase in the incidence of gingivitis or stomatitis with this sustained elevation of bismuth in the blood stream?

DR. JOSEPH GRINDON, St. Louis: The advocacy by the authors of the combined use of these two preparations in early syphilis is convincing, but I ask whether in late or latent syphilis, and in the absence of any immediately threatening lesion, it presents any advantage.

DR. HARRY M. ROBINSON, Baltimore: I should like to ask the authors about dermatitis reactions caused by injections of this bismuth compound of 2 decigrams a week. Quite a few cases of dermatitis are found in our clinic. They are of the lichenoid or eczematous types, not exfoliative but still very annoying. I should like to know whether with this high concentration of bismuth the dermatitis is of any more or less frequent occurrence.

DR. ELMORE B. TAUBER, Cincinnati: Before the insoluble preparations of bismuth are relegated to the background and either the oral administrations or the soluble ones are adopted, I want to make a plea for bismuth subsalicylate if it is placed in the proper vehicle. Unfortunately the vehicles that have been placed on the market have been mineral oils and other oils which are the ones when deposited intramuscularly that act as a foreign body and cause a fibrosis with a consequent lowering of the amount of bismuth absorbed. In the last five or six years I have used a preparation of bismuth subsalicylate incorporated in a vegetable compound which is simple, easy to make, with no pain resulting, and this compound is nothing but Crisco, which has stearin in it and which is absorbed easily; and shortly afterward, not within twenty-four to forty-eight hours but within a week, the excretion of from 2 to 3 mg. of bismuth in the urine is observed. It is inexpensive, painless and equal to or better than any preparation that I know on the market. I should also like to ask whether the authors have had any use of oral bismuth.

DR. HAROLD N. COLE, Cleveland: Naturally, one would hesitate to employ dosages of bismuth that would continuously cause an excretion of 15 mg. of metallic bismuth a day in the urine. To Dr. Grindon I will say that this is designed principally for acute syphilis or situations in which a rapid bismuth effect is desired. I do not think it is indicated in late syphilis or for old syphilitic patients but in these acute cases. We have not seen any bad effects from this therapy in the limited number of cases in which we have employed it. Naturally, patients who are getting a dosage of this sort should be watched closely. Probably the first symptom that one would note would be a bismuth line. It is true that once in a while

one encounters a dermatitis from bismuth, but it is uncommon, nothing like the frequency that is encountered with preparations of the arsphenamines that are on the market. With regard to Dr. Tauber's notation about Crisco, a Cincinnati-made product, I would say that we have not used it but that, as he knows, all suspensions of bismuth that are on the market today are in vegetable oils; mineral oils are not employed any more. The reason we are suggesting this type of therapy is that with the water soluble preparations one does get a certain amount of irritation and discomfort, and while it may be justifiable for one or two or three weeks while one is anxious to get them under control, it probably would not be possible to get these patients to continue coming in twice a week for a comparatively irritating preparation as compared to the effects of bismuth subsalicylate. On that account we feel that it would be preferable to change over gradually to this other compound. I should like to say that sobisminol has given the highest excretion of bismuth in the urine of any preparation that we have worked with. We have used this preparation some by mouth in a form that Dr. Hanzlik has worked out. It seems as though from our limited experience there is little or no discomfort from its oral use, and one gets an excretion that compares well with that of iodobismitol. We have had insufficient experience, however, to give any final results on it.

## DIMENSIONS OF THE RED CELLS IN FAMILIAL HEMOLYTIC ANEMIA

WITH PARTICULAR REFERENCE TO  
ATYPICAL CASES

JOSEPH M. HILL, M.D.

DALLAS, TEXAS

Repeated complete measurements of the red cells have been made in seven cases of familial hemolytic anemia studied in Baylor University Hospital during the past two years. The results permit some definite conclusions with regard to the diagnostic value of the size and shape of the erythrocytes (spherocytosis). Furthermore, changes in these dimensions during the course of the disease have been studied in relation to clinical variations, onset of crisis, erythropoiesis and splenectomy. Interpretation of the modifications of corpuscular size and form is based on determination of the normal range of these qualities and consideration of pathologic factors known to affect them.

Alteration of the dimensions of the red cells in familial hemolytic anemia has been recognized almost as long as the disease entity itself. Chauffard<sup>1</sup> in 1907 first noted the decreased diameter, subsequently regarded as the chief characteristic by most writers, including Naegli,<sup>2</sup> Dawson<sup>3</sup> and Haden.<sup>4</sup> Increased thickness and decreased diameter were said by Naegli to be the fundamental inherited feature of the disease. Gänsslen<sup>5</sup> first related this change in shape to increase in fragility. Meulengracht<sup>6</sup> and von Boros<sup>7</sup> expressed

the opinion that spherocytosis is not a specific feature of familial icterus but a regeneration phenomenon unrelated to fragility.

Von Boros<sup>8</sup> and Haden<sup>9</sup> assumed the red cell to be a cylinder for purposes of calculation and expressed the volume-thickness relationship by an index. Haden presented conclusive experimental evidence that there

Chart 1.—Progress of the disease in case 1. Read the values for the reticulocytes and the icterus index directly from scale. For the red cell count shift the decimal one place to the left (divide by 10) and read in millions.

is a direct relationship between the degree of approach to sphericity as expressed by this index and the fragility of the red cells and stated that microspherocytosis is the fundamental variation from normal, all other phenomena of the disease being secondary. Castle<sup>10</sup> confirmed this mechanism of fragility and ruled out differences in osmotic behavior as a possible factor. He also devised an absolute rather than a relative index of sphericity, expressing as a percentage the difference between the corpuscular volume and the volume of a sphere of equal surface.

The primary role of the spleen in this disease has been upheld by many hematologists. Doan, Curtis and Wiseman<sup>11</sup> in 1935 recognized spherocytosis but found that the erythrocytes approached the normal form after splenectomy. Vaughan<sup>12</sup> suggested that both erythropoiesis and splenic function are at fault but stated that spherocytosis is not the fundamental abnormality.

Momigliano-Levi and Bairati<sup>13</sup> expressed the opinion that the bone marrow can produce normal cells when relieved of the excessive load of increased destruction in the spleen.

Josephs<sup>14</sup> suggested that an antihemolytic substance normally present to maintain the equilibrium between erythropoiesis and destruction may be absent in sickle cell anemia and hemolytic jaundice.

Since the validity of the results reported in this series of cases depends on the technic employed, a brief statement of method is essential.

#### METHOD

In determining complete dimensions of the erythrocytes, the red cell count, the mean cell diameter and the percentage of packed cells (hematocrit) must be obtained. Simultaneous determination of the hemoglobin is also desirable.

In enumerating the red cells all known precautions with regard to the use of certified equipment, proper shaking and the counting of a large number of cells were observed. Blood was taken from the same sample as that examined with the hematocrit, and 320 small squares were counted.

The mean cell diameter was obtained by a modification of the technic of Price-Jones.<sup>15</sup> The corpuscles were projected at a magnification of exactly 3,000 diameters onto a white target and were measured by fitting to the images circles drawn to a proper scale on white cards. An effective numerical aperture of 1.30 gave full resolution. At least 500 cells were measured in each instance.

For hematocrit determinations Magath tubes were used throughout, and in the later cases duplicate determinations with Wintrobe tubes were also made. Heparin was used as an anticoagulant, but in the duplicates 1.4 per cent sodium oxalate was employed with identical results. All specimens were centrifuged for at least one hour at a minimum speed of 2,500 revolutions a minute. Constant red cell volume was always obtained under these conditions in later experiments. Increasing the speed of centrifugation to 4,500 revolutions showed no significant change in the packing of the red cells.

Chart 2.—Progress of the disease in case 2.

Only rarely can all the diagnostic criteria of familial hemolytic anemia be found in one case. In the present study diagnosis was based on several considerations. First, the familial character was considered established if undoubted spherocytosis was found in other members of the family or if a sufficiently definite history of splenomegaly, anemia or jaundice was obtained. Second, the hemolytic character of the anemia was determined

15. Price-Jones, Cecil: *Red Blood Cell Diameters*, New York, Oxford University Press, 1933.

by a study of the state of equilibrium between production and destruction of red cells, indicated by use of laboratory procedures as outlined in the exhibit.<sup>16</sup> Third, repeated measurement of the red cells with the finding of spherocytosis, microcytosis or both on at least one occasion was regarded as most important. Finally, confirmation of the diagnosis was often made

Chart 3.—Progress of the disease in case 3.

possible by examination of the spleen, by the clinical course before and after splenectomy or, in the event of death, by postmortem examination. Studies of the sternal marrow were also employed, particularly in ruling out leukemia.

In expressing corpuscular shape in terms of its approach to spherical form, neither Haden nor Castle reported the limits of physiologic range. Because the biconcave form of the red cell is well adapted to changes in volume and osmotic variations in the blood are known to be accompanied by a shift of water across the red cell membrane, definite alteration in erythro-

TABLE 1.—Measurements of the Red Cells, Case 1\*

Day in Hospital	M.C.V., Cu. Microns	M.C.D., Cu. Microns	M.C.T., Microns	Castle's Index	Haden's Index

1 year later.....	90	6.4	2.8	38.3	1.7

\* Note that the lower the value of Castle's index, the greater the sphericity, whereas in the case of Haden's index the reverse is true. In the tables M.C.V. indicates mean corpuscular volume; M.C.D., mean corpuscular diameter; M.C.T., mean corpuscular thickness; Castle's index, Castle's absolute index of sphericity, and Haden's index, Haden's volume-thickness index.

cytic form must occur. In the first fifteen normal persons of a series now being studied, this variation was borne out. The volume-thickness index ranged from 0.95 to 1.4 with a mean of 1.18, and the absolute index of sphericity varied from 46.4 to 68.6 with a mean of 57.6. The former differs by a significant amount from Haden's normal value of 1, while the latter, because of the greater numerical range, is in practical agreement with Castle's normal value of 59. In addition, similar physiologic variations were found in the same person at different times, for example after exercise.

16. Hill, J. M., and Waters, Lewis: Hematologic Exhibit: IV. The Diagnosis of Hemolytic Anemia, A. M. A. Meeting, San Francisco, June 1938. Scientific Exhibit at the Eighty-Ninth Annual Session of the American Medical Association.

Although Price-Jones, Vaughan and Goddard<sup>17</sup> studied the diameter, volume and thickness of the red cells in 100 normal persons, no calculation of sphericity was made. Their mean diameter of 7.17 microns, however, did not differ significantly from our mean of 7.02 microns. Furthermore, calculation of sphericity from their limits of diameter and volume indicate a possible range as great as ours. Consequently in the series of cases herein reported values above 1.5 for volume-thickness index or below 45 for Castle's absolute index were regarded as definite evidence of spherocytosis.

TABLE 2.—Measurements of the Red Cells, Case 2

Day in Hospital	M.C.V., Cu. Microns	M.C.D., Cu. Microns	M.C.T., Microns	Castle's Index	Haden's Index

32.....	90	6.5	2.6	41.4	1.6
45.....	75	6.4	2.3	47	1.4
50.....	92	6.4	2.7	38	1.7

Values near the limit of normal were looked on with suspicion, especially with small diameters or marked variation in apparent thickness in the smears.

CASE 1.—K. M., a white boy aged 7, had the acute febrile type of hemolytic anemia, with macrocytosis followed by clinical cure and microcytosis after splenectomy, as illustrated in chart 1. Clinical study showed jaundice, anemia and a palpable spleen. A family history of jaundice was established. The measurements of the red cells are listed in table 1.

CASE 2.—J. T. B., a white boy aged 12, had a moderately severe type of red cell destruction, with clinical features of slight jaundice, splenomegaly, hepatomegaly and an unhealed chronic ulcer of the leg. Hemolytic icterus in his mother was verified by postmortem examination. Chart 2 illustrates the progress of the disease and the response to splenectomy, and table 2 shows the successive dimensions of the red cells.

Chart 4.—Progress of the disease in case 4.

CASE 3.—M. C., a white girl aged 14, had an acute hemolytic crisis, as demonstrated in chart 3. No significant family history could be discovered. Clinical study disclosed transient neurologic symptoms, including hemiplegia and paralysis of the left arm. There were pallor, icterus and bleeding gums. The spleen was not palpable. The series of red cell measurements is given in table 3. Death occurred a few hours after splenectomy. Postmortem examination showed peculiar hyaline thrombi in a large number of the smaller vessels of all the sections examined,

17. Price-Jones, Cecil; Vaughan, J. M., and Goddard, H. M.: Normal Hematologic Standards, J. Path. & Bact. 40: 503-519 (May) 1935.

including sections of the heart, brain, liver and spleen. The spleen was otherwise characteristic of familial hemolytic anemia.

CASE 4.—A. T., a white woman aged 54, had slight jaundice, scanty urination, weakness, dyspnea and fever. The spleen was not palpable. A significant family history was demonstrated only through examination of her son's corpuscles. The acuteness of the hemolytic crisis as well as the favorable effect of

again but was refused, and the patient returned home to die two weeks later. The diagnosis was familial hemolytic anemia complicated by cirrhosis of the liver giving a clinical picture identical with Banti's syndrome.

CASE 7.—J. B. A., a white man aged 60, an outpatient, had had intermittent episodes of splenomegaly, anemia and sometimes jaundice since the age of 10. In the five years during which he was under observation, the anemia was only moderate, with the red cell count varying between 3,800,000 and 4,400,000 and the percentage of reticulocytes from 7 to 11. The red corpuscles were constantly microcytic, with an average mean cell

Chart 5.—Progress of the disease in case 5.

splenectomy is easily seen in chart 4. The spleen showed the characteristic enlargement and microscopic picture. The corpuscular dimensions are shown in table 4.

CASE 5.—H. B. W., a white man aged 25, a brother of patient 6, had had previous attacks of anemia, jaundice and splenomegaly. Clinical investigation showed marked enlargement of the spleen and liver, general anasarca and extreme pallor. The results of laboratory tests are given in chart 5 and the complete measurements of the red cells in table 5. The patient refused splenectomy until he felt definitely worse. He died twelve hours after operation. The spleen differed from that in the other cases only in being larger and more heavily loaded with hemosiderin and in showing slight fibrosis. Post-mortem examination showed enlargement of the liver with lobular cirrhosis, bronchopneumonia and early diffuse peritonitis.

CASE 6.—B. M. W., a white youth aged 19, a brother of patient 5, had an identical history and the same clinical appearances. The course of the illness is shown in chart 6. During the first admission, which antedated that of his brother, definite microcytosis and moderate spherocytosis were apparent, as shown

TABLE 3.—Measurements of the Red Cells, Case 3

Day in Hospital	M.C.V., Cu. Microns	M.C.D., Cu. Microns	M.C.T., Microns	Castle's Index	Haden's Index

8.....	93.4	7.2	2.2	56	1.23
9.....	131	6.55	3.8	28.5	2.33

in table 6. At the second admission, one year later, with the anemia much worse a definite macrocytic tendency was apparent, with abnormal thinness of the red cells. Gastric analysis gave negative results, and leukopenia was present. The white cell count varied from 3,400 to 1,350 during this admission. After failure of transfusion and intramuscular administration of liver extract to arrest his progressive anemia, two doses of 20 cc. of liver extract were given intravenously in an attempt to unmask the possible complicating macrocytic factor of cirrhosis of the liver and to remove any inhibition of erythrocytic maturation. The dramatic response of the reticulocytes, shown in chart 6, was accompanied by progressive reduction in the diameter of the cells, with a slight increase in thickness and fragility but with no improvement of the anemia. Transfusion was of no avail, and the increased destruction of erythrocytes was reflected in the increased icterus index. Splenectomy was recommended

TABLE 4.—Measurements of the Red Cells, Case 4

Day in Hospital	M.C.V., Cu. Microns	M.C.D., Cu. Microns	M.C.T., Microns	Castle's Index	Haden's Index

diameter of 6.5 microns. The degree of spherocytosis varied from borderline normal to definitely spheroid. The volume-thickness index varied from 1.4 to 1.9 and Castle's index from 48 to 36. The only atypical feature was the presence of a leukemoid blood picture during the period of observation, with a moderate number of normoblasts, erythroblasts, myelocytes and myeloblasts. The diagnosis was familial hemolytic anemia with ectopic hemopoiesis resulting in a leukemoid blood picture.

COMMENT

The finding of considerable variation in the volume-thickness relationship of normal red cells, as expressed by Haden's or Castle's method, is by no means an exception to the usual biologic rule. Furthermore, such variation is probably an expression of functional changes in the corpuscles of an individual as well as a normal morphologic difference between individuals. It is also in complete harmony with the limits of normal established for cell volume and diameter.

Apparently this series of cases represents the first determination of the range of the indexes of Castle and Haden. A comparable variation in thickness of

Chart 6.—Progress of the disease in case 6.

the red cells has already been reported by Price-Jones, Vaughan and Goddard, in which they found no correlation with the diameter. Unfortunately, no calculation of sphericity was made.

The interpretation of values for erythrocytic sphericity must be made with due regard to the normal limits as well as to possible physiologic variations in

the individual case. Many values previously reported as indicative of spherocytosis were undoubtedly within the normal range.

In the present series of cases the effect of physiologic changes probably accounted for a large measure of the variations seen. However, there was an undoubted general tendency to spherocytosis, since in every case but one there was at least one occasion when definite spherocytosis occurred. From this it is evident that only repeated examinations are of diagnostic significance unless values well beyond the normal range are obtained.

Decrease in the diameter of the erythrocytes appeared to be even more constant. In addition, a fairly definite relationship to spherocytosis was evident. As a rule, the thickest cells had the smallest diameters.

The one notable exception to microcytosis occurred in the fairly typical case 1. In this case a definitely macrocytic spherocytic corpuscle of enormous volume was seen in the first examination. The mechanism of production of this atypical variety of cell is not well understood. However, the explanation of Davidson

and Fullerton<sup>18</sup> is probably the most satisfactory, according to which megaloblastic transformation of the marrow is assumed as a result of hyper-regeneration. A rather prolonged hemolytic crisis of relatively severe degree, as seen in case 1, is apparently the stimulus to this type of response.

Another complicating factor must be considered in the diagnosis in rare atypical cases, namely coincident pathologic processes which tend to result in the formation of abnormally thin or abnormally large red cells. For example, cirrhosis of the liver exhibits both of these tendencies. Cases 5 and 6 evidently represent slightly different degrees of this type of complication. When studied together, the cases of these two brothers present conclusive evidence of two conditions tending to produce anemia but mutually opposed in their effect on corpuscular size and shape. In case 5 postmortem examination showed cirrhosis of the liver, while in case 6 the effect of liver therapy was definitely indicative of a similar mechanism. In addition, the unmasking of microcytosis corroborates the diagnosis of familial hemolytic anemia.

Finally, this study fails to reveal any correlation between the degree of spherocytosis and the severity of the disease. Neither was a definite relationship established between spheroid form and the onset of crisis, the rapidity of regeneration of the red cells or even the effect of splenectomy.

## SUMMARY AND CONCLUSIONS

Microcytosis was found on at least one occasion in six of seven cases of familial hemolytic anemia, while spherocytosis was found in five cases.

Spherocytosis may be absent in the presence of complicating factors such as cirrhosis of the liver.

Macrocytosis was observed in one case during crisis.

No significant correlation could be established between spherocytosis and the severity of the disease, onset of crisis, rapidity of regeneration of the red cells or effect of splenectomy.

## ABSTRACT OF DISCUSSION

DR. RUSSELL L. HADEN, Cleveland: Dr. Hill has verified the observation that the increased tendency to hemolysis of red cells in congenital hemolytic jaundice is dependent on the spherocytic shape of the cell. I have recently studied a patient, however, who had the typical clinical picture of congenital hemolytic jaundice and spherocytosis of the red cells without increased fragility. I cannot explain this observation. Several factors influence the shape of the cell in congenital hemolytic jaundice. The simultaneous occurrence of an iron deficiency will flatten the spherocyte. If a deficiency in the erythrocyte-maturing factor supplied by liver occurs, the cell becomes larger. If a patient has anemia with cells of very small diameter, the disease is usually congenital hemolytic icterus and should be treated by splenectomy. On the other hand, hemolytic anemia with cells of large diameter should seldom be treated surgically. Dameshek has shown recently that under certain conditions, such as infection, the shape of the cell may change so that at times it is sufficiently spherocytic to be more fragile than normal. Thus the spherocytosis does not depend on heredity alone.

DR. M. C. RIDDLE, Portland, Ore.: Dr. Hill's paper points out that one cannot be too complacent in one's fixed ideas on the hemologic pictures of the various disorders discussed. It is extremely important that the clinical features of these diseases should be taken into account as well as the laboratory features. I have under observation a patient with familial jaundice which illustrates the features discussed. This patient has passed through three phases so far as the hemologic picture is concerned. In the first phase the typical hemologic picture of familial jaundice was present. Then there developed a leukemoid picture with a white count in the vicinity of 40,000, with considerable numbers of immature myeloid cells. In the third phase leukopenia and pronounced macrocytosis developed. The blood film was indistinguishable from that of pernicious anemia. This macrocytosis responded to the use of liver extract. I accounted for this response in much the manner in which Dr. Haden accounted for the macrocytosis discussed by Dr. Hill.

DR. JOSEPH M. HILL, Dallas, Texas: The time available did not permit a discussion of fragility. It is well known that undoubted hemolytic anemia may not be accompanied by increased fragility. This can be explained by the absence of spherocytosis at least during certain phases. I did find a rather definite relation between spherocytosis and fragility; in fact, it was more definite than the relation of clinical features and spheroid red cells. I believe that the use of liver therapy for this type of anemia is rational, since depletion of the stored erythrocyte-maturing factor apparently can result from prolonged excessive demand incident to increased erythropoiesis. This situation is apt to occur when the disease is unrecognized and untreated and there is damage to the liver. With regard to the leukemoid blood picture associated with this disease, there are probably two types: first, the acute crisis representing an outpouring of cells from the bone marrow and, second, the type that occurred in case 7. I believe that in this instance, with a compensated form of hemolytic jaundice, ectopic hemopoiesis resulted in lack of normal control of blood cell output. It may be difficult in such cases to differentiate the disease from myelogenous leukemia. The patient has been followed for five years, and I feel certain that he does not have leukemia, although at one time he was treated for it.

## THE OUTLOOK IN THROMBO-ANGIITIS OBLITERANS

BAYARD T. HORTON, M.D.  
ROCHESTER, MINN.

In the past decade I frequently have had anxious patients with thrombo-angiitis obliterans ask the question What is the outlook in my case? Hence the title of this paper. In an attempt to answer the question in such a manner that it may be of some service both to patients and to fellow workers in the field, I have carefully reviewed all the cases of thrombo-angiitis obliterans that have been observed at the Mayo Clinic from 1907 to 1937 inclusive. I have myself observed and studied a large number of these cases.

The past decade has witnessed marked changes in the attitude of physicians toward thrombo-angiitis obliterans largely because of a better understanding of the disease. Prior to this time the diagnosis of thrombo-

20 and 50 years. In spite of the fact that it was formerly supposed to occur almost exclusively among Jews, it is now known to affect persons of all races. The cause of the disease has not been established. Its usual course is rather slow. As a rule the main vessels of the feet and legs are involved early, those in the upper extremities later.

The disease is characterized by a chronic relapsing lesion of the vessels in which the occlusive process and the development of collateral circulation struggle for supremacy. The element of time is most important in this struggle, since on it rests the preservation of the parts. If the intervals between relapses are short and the time for the development of collateral circulation is inadequate, trophic changes and gangrene are likely to ensue. Conversely, if the intervals between relapses are long, the collateral circulation becomes adequate and a sufficient supply of blood to the distal parts is assured. The first consideration regarding prognosis is therefore the frequency of exacerbations of the disease. Experience in a large number of cases shows clearly that the belief that amputation invariably will be necessary is not justified.

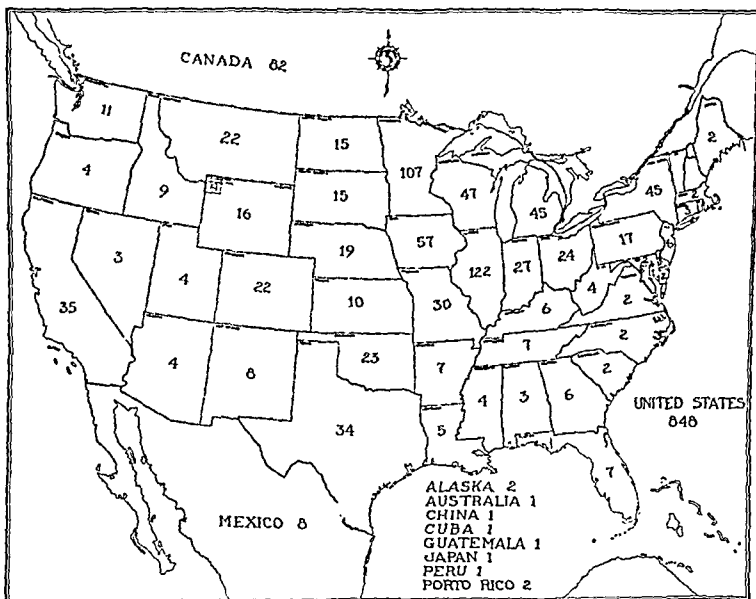

Fig. 1.—Geographic distribution of cases of thrombo-angiitis obliterans.

angiitis obliterans carried with it the implication that amputation of one or both lower extremities would follow inevitably and, once the diagnosis had been established, it was suggested that amputation of the involved extremity be carried out promptly. For example Buerger,<sup>1</sup> in his book published in 1924, said that "amputation just above the middle of the leg" was performed in one case "because the little toe looked as though it was going to die off." At the clinic we have become more optimistic from year to year regarding the disease, and we feel that, if the diagnosis is made early and if the patient follows the thorough instructions which are given regarding the care of his extremities, he stands a good chance of continuing to walk on two feet throughout life.

Thrombo-angiitis obliterans is a chronic occlusive arterial disease involving chiefly the extremities and affecting, for the most part, men between the ages of

### BASIS OF PRESENT STUDY

In the thirty-one years from 1907 to 1937 inclusive, 1,374 patients with thrombo-angiitis obliterans registered at the clinic. But since 426 of these patients registered more than once during this period, and some of them as many as ten times, the present study will be confined to the 948 individual patients represented (table 1). Throughout this report considerable material will be presented which bears on the old question of the relative susceptibility to this disease manifested by males and females and by Jews and Gentiles.

### GEOGRAPHIC DISTRIBUTION

The patients in this series came from every state in the Union except Rhode Island, Vermont and New Hampshire; in addition there were patients from Canada, Mexico, Alaska, Australia, China, Cuba, Guatemala, Japan, Peru and Porto Rico (fig. 1). They came from practically every walk of life. The same fundamental pathologic process was present in all cases and the signs and symptoms, as well as the clinical course, were strikingly similar. It is interesting to note that, while in the majority of cases of thrombo-angiitis obliterans the symptoms begin during the winter months, in this study the incidence of amputations in the warmer sections of the country, such as Florida and California, was as high as that observed in Minnesota and Canada (fig. 2). Therefore, in spite of the fact that patients went to live in warm sections of the country after having been observed at the clinic, amputations were still necessary. The explanation of this probably is that vasospasm in the collateral circulation does not disappear until the environmental temperature is 82 F. or above, as our studies at the clinic have proved. It is difficult to find in the United States a place where such a temperature is maintained.

### AGE, SEX AND RACE

The distribution by age and sex is represented in table 2. The mean age of all patients was 41.8 years. More than 70 per cent of the 948 patients were in the

From the Division of Medicine, the Mayo Clinic.  
Read before the Section on Practice of Medicine at the Eighty-Ninth Annual Session of the American Medical Association, San Francisco, June 16, 1938.  
1. Buerger, quoted by Samuels, S. S.: *The Diagnosis and Treatment of Diseases of the Peripheral Arteries*, New York, Oxford University Press, 1936, p. 73.

third and fourth decades of life, the ages for the entire series varying from 17 to 73 years. The sex incidence is likewise of interest. Of the 948 patients twenty-one were women, which indicates an incidence of approximately 98 per cent in men.

I know of no other disease in which such common tissues as the veins and arteries are involved that is so exclusively confined to one sex as is thrombo-angiitis obliterans. No adequate explanation has yet been brought forth to account for this most unusual sex distribution. Too few cases of thrombo-angiitis obliterans have thus far been observed in women for one to compare adequately the severity of the disease as it affects them with its severity in the case of men. I have been under the impression that the disease runs a milder course in women than in men, but more cases will have to be observed for a longer period before conclusions in this respect can be drawn.

Of the twenty-one women patients, five were Jewish and sixteen were Gentiles. Of the 927 men, 257 were Jews and 670 were Gentiles. Thus roughly 28 per cent of the 948 patients were Jews and 72 per cent were Gentiles. In earlier reports<sup>2</sup> from the clinic, 55 per cent of the patients were Jews and 45 per cent were Gentiles. Thus far we have not observed thrombo-angiitis obliterans affecting a full-blooded Negro, although such cases have been observed elsewhere; one of our patients was, however, part Negro. More than twenty-eight different nationalities were represented in this series.

#### RACE AND DEGREE OF SMOKING

If a patient smoked five cigarettes a day he was listed as a grade 1 smoker, if ten cigarettes a day as a grade 2 smoker, if fifteen cigarettes a day as a grade 3 smoker and if twenty cigarettes or more a day as a grade 4 smoker (table 3). Many of the grade 4 smokers used as many as sixty cigarettes a day. One patient, for example, smoked at least twenty cigarettes before breakfast. Of the total of 948 patients who had thrombo-angiitis obliterans, 93 per cent were cigarette smokers; in 66 per cent of the cases the degree of smoking was graded 3 or 4.

Of the 262 Jews, 238 were smokers (table 3). Sixty-five of them were grade 1 or grade 2 smokers, and of these twenty-five, or 38 per cent, underwent amputation. Of the 173 grade 3 or grade 4 smokers fifty-eight, or 33 per cent, were subjected to amputation. Thus of the 238 Jewish patients who had thrombo-angiitis obliterans and who smoked, eighty-three, or 35 per cent, underwent amputation, whereas only 21 per cent of the nonsmokers were subjected to amputation. This report includes amputations elsewhere as well as at the clinic.

Of the 686 Gentile patients, 642 were smokers. Ninety of the 189 grade 1 or grade 2 smokers (48 per cent) were subjected to amputation; of the 453 grade 3 or grade 4 smokers 207 (46 per cent) underwent amputation. Of the forty-four Gentile patients who were nonsmokers sixteen, or 36.4 per cent, underwent amputation. Thus of all Gentiles who smoked

297, or 46 per cent, underwent amputation, whereas only 36.4 per cent of the nonsmokers were subjected to amputation.

It has been accepted generally that thrombo-angiitis obliterans is somewhat more severe among the Jews than among representatives of other races. This does not seem to be borne out by the present studies. Of the 262 Jews 33.6 per cent underwent amputation, whereas of the 686 Gentiles 45.6 per cent were subjected to amputation (table 3). These figures are for both sexes and for amputation performed both at the clinic and elsewhere.

The present study tends to indicate, however, that amputations were less frequent among nonsmokers. It has been difficult to persuade patients with thrombo-angiitis obliterans to stop smoking. In the past ten years numerous experimental studies have been reported in the American literature, which establish rather definitely that the use of tobacco does produce some vasospastic effects. Lampson,<sup>3</sup> Maddock and his

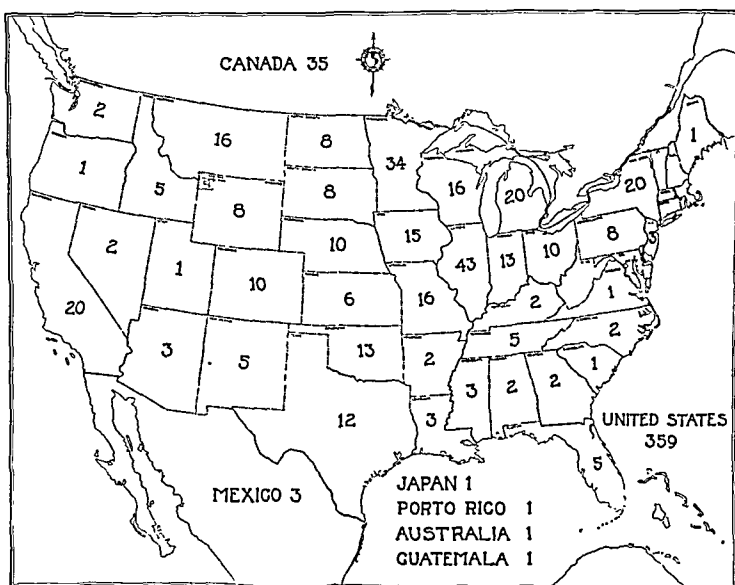

Fig. 2.—Geographic distribution according to amputations.

co-workers,<sup>4</sup> Barker<sup>5</sup> at the Mayo Clinic, as well as Wright and Moffat<sup>6</sup> and Johnson,<sup>7</sup> have contributed important articles from this standpoint. Haggard and Greenberg<sup>8</sup> noted a definite elevation of the blood sugar following the use of tobacco. They were of the opinion that the mild hyperglycemic effect, as well as the effect on the blood pressure, might be a secondary result of the adrenal stimulation which is brought about by the action of nicotine on the sympathetic nerves and which results in an increased secretion of epinephrine. Herrell<sup>9</sup> recently has reported the case of a man, aged 57,

whose systolic and diastolic blood pressure invariably became markedly elevated and whose retinal arteries became constricted following the smoking of a cigaret.

AMPUTATIONS

It will be noted in table 1 and in figure 3 that according to the total registrations 15.6 per cent of the patients underwent amputation at the clinic. One hundred and seventy-eight of the patients were subjected to one or more amputations at the clinic, the total number of amputations performed being 214. Six of these patients were women, 172 were men. No amputations for thrombo-angiitis obliterans were carried out at the clinic from 1907 to 1916 inclusive, and the percentage of amputations from 1928 to 1937 inclusive was definitely less than during the previous ten years. Later in this report it will become evident from the statistics concerning amputation that progress has been made in the nonsurgical management of this disease.

*Major and Minor Amputations.*—In this study the loss of a finger or a toe was considered to constitute a minor amputation; the loss of a foot, a leg or a hand was considered a major amputation. Eighty-eight Jews and 313 Gentiles underwent amputation. The percentage of each of these two racial groups who were subjected respectively to major and to minor amputa-

\* At the clinic.

tion is given in table 3. Of the total of 401 patients who underwent amputation 276, or 69 per cent, underwent major amputations; the remaining 31 per cent had minor amputations (table 3).

Seventy-one per cent of all amputations at the clinic for thrombo-angiitis obliterans from 1918 to 1927 inclusive were major amputations, whereas only 63 per cent of all amputations from 1928 to 1937 inclusive were major amputations. It is still more encouraging to note that during the past five years (1933-1937)

only 48 per cent of amputations at the clinic were of the major type. This indicates definite progress in the medical and surgical management of this disease.

*Amputations at Three, Five and Ten Year Periods After the Onset of the Disease.*—In this phase of the study patients were divided into three, five and ten year groups, each group indicating the period of time which had elapsed since the onset of the condition. Thus of

Per cent.....	97.8		2.2		100.0	

the 828 subjects in the three year group 694 (84 per cent) were followed for a period of three years from the onset of thrombo-angiitis obliterans. Of these 694, 215 (31 per cent) were subjected to amputation (table 4). This would indicate that approximately 70 per cent of patients who have thrombo-angiitis obliterans will go for three years after the onset of the disease without amputation being necessary. In the five year group 628 (80 per cent) of the 785 patients were traced and, of these, 248 (39.5 per cent) underwent amputations. This in turn would indicate that approximately 60 per cent of patients who have thrombo-angiitis obliterans will go for five years without the necessity of amputation. In the ten year group 334 (77 per cent) of the 433 patients were traced, and of these 59.9 per cent had amputations. This would indicate that approximately 40 per cent of patients who have thrombo-angiitis obliterans will go for ten years after the onset of the disease without amputation. These figures perhaps give a better insight into the outlook in thrombo-angiitis obliterans than anything else.

*Bilateral Major Amputations.*—Of the 948 patients, eighty-five underwent bilateral amputation of the legs; sixteen of these patients were Jews and sixty-nine were Gentiles. Eleven bilateral amputations were carried out at the clinic, all of the patients being Gentiles. Thirty-five per cent of these eighty-five patients who underwent bilateral amputations live in warm climates. Eighteen of the eighty-five are dead. At the clinic we have never had to amputate a hand because of thrombo-angiitis obliterans, but in this series of cases the hand of one subject had been amputated prior to his admission to the clinic; the hand of a second patient and both hands as well as both legs of a third patient were amputated after the patients left the clinic.

PHYSICIANS WITH THROMBO-ANGIITIS OBLITERANS

Twenty-two of the 948 patients were physicians, fifteen being Gentiles and seven Jews. Two of these twenty-two physicians underwent amputation, each losing a leg, and one of them later underwent lumbar sympathetic ganglionectomy at the clinic. Three of the twenty-two underwent bilateral sympathetic ganglionectomy at the clinic; not one of these has been subjected

to a major amputation since. One patient who had gangrene of the toes at the time of sympathectomy has since had the toes removed. Four of these twenty-two physicians are dead, one dying of cancer; the cause of death in the other three cases was not stated.

#### COMPLICATIONS

**Thrombo-Angiitis Obliterans and Hypertension.**—Of the 948 patients who had thrombo-angiitis obliterans 147 (15.5 per cent) had hypertension. Forty-three of the 147 are dead and twenty-two of the 147 underwent amputation.

**Thrombo-Angiitis Obliterans and Diabetes.**—Ten of the patients with thrombo-angiitis obliterans also had diabetes, the diabetes being relatively mild in nine cases. Six of the ten patients were Jews. All ten patients used tobacco averaging from fifteen to forty cigarets a day.

	Gentiles.....	213	68.0	100	32.0

One of the Jewish patients had a toe amputated, one of the Gentiles a leg. One of the ten died a morphine addict.

The incidence of amputation in this small group was not any greater than in the group of patients who did not have diabetes. The part diabetes mellitus plays in the presence of thrombo-angiitis obliterans is not definitely known, but the indications are that if the diabetes is not adequately controlled it may tend to aggravate the course of the thrombo-angiitis obliterans.

#### SYMPATHECTOMY IN THROMBO-ANGIITIS OBLITERANS

One hundred and ninety-three of the 948 patients underwent either cervicothoracic or lumbar sympathectomy. Twenty-eight of the patients were Jews, 165 Gentiles. Ten of the Jewish patients later underwent amputation (eight major and two minor) and forty of the Gentile patients later underwent amputation (twenty major and twenty minor). Of the total 193 patients in this group, therefore, fifty (26 per cent) were later subjected to amputation. Five of twenty-one women patients underwent bilateral lum-

bar sympathetic ganglionectomy and one of the five also underwent cervicothoracic sympathetic ganglionectomy. Eight of these twenty-one women had amputations. Four of them were nonsmokers (two major amputations, two minor amputations); the other four were smokers and all underwent minor amputation.

It is well recognized that sympathectomy does not cure thrombo-angiitis obliterans. Probably it does not

even alter the course of the disease in the blood vessels. It does, however, bring about the maximal blood flow to the sympathectomized extremities and for that reason is still the most logical surgical procedure in properly selected cases for increasing the blood supply.

#### CAUSES OF DEATH

One hundred and seventy-five of the 948 patients with thrombo-angiitis obliterans are known to be dead. Five of these were women. It is interesting to note that coronary heart disease ranked first as the cause of death, forty-seven (27 per cent) of the 175 patients having died of it. An additional twelve patients died of cerebral hemorrhage. Twelve patients died with gangrene or following amputation for gangrene, and seven died of fatal pulmonary embolism. The others died of known but unrelated causes.

Fig. 3.—Incidence of amputations for thrombo-angiitis obliterans according to registrations.

#### PROGNOSIS

While in this study I have been able to tabulate many facts regarding this series of cases of thrombo-angiitis, no one could ever tabulate the loss of time and money, the pain and suffering and the tragedy of the loss of limbs incurred by these unfortunate persons. When one contemplates the large number of those who underwent major amputation, frequently of both legs and

occasionally of both arms, and who yet were able to carry on with a smile, one cannot help but think of Tennyson's lines "That men may rise on stepping-stones of their dead selves to higher things."

What, then, are the important factors which determine whether a person with thrombo-angiitis obliterans will live out his life expectancy walking on two feet, or whether he will fall into the unfortunate group whose extremities will have to be amputated? I believe that early diagnosis and thorough education of the patient concerning the nature of his disease and the care of his extremities will accomplish more in this respect than all other factors at the physician's command. Early diagnosis is important in order that the individual can avoid unnecessary delay in carrying out prophylactic measures to prevent the occurrence of gangrene. When it is recalled that at least 20 per cent of the patients who have come to the clinic with gangrene have had incisions made or nails removed for supposed infections of the digits, it becomes apparent that a working knowledge of the early signs and symptoms of thrombo-angiitis obliterans still is not widespread among members of the medical profession. The most frequent errors in diagnosis consist in mistaking claudication in the foot for evidence of arthritis or fallen arches and the abnormal rubor of the toes for evidence of infection. Pain in the arch of the foot on exercise suggests a structural defect in the bony support; hence most patients with thrombo-angiitis obliterans have had three or four pairs of arch supporters. Fortunately this error is much less evident now than it was ten years ago.

The essential point to establish, in the presence of symptoms referable to the hands, feet or legs, is whether the complaint is attributable to disease of the vessels and, if it is, whether the process is occlusive or vasomotor. The distinction between occlusive arterial disease and vasomotor disturbances can be made with accuracy in 95 per cent of cases by determining by simple palpation the presence or absence of pulsations in the four palpable arteries of the leg or in the two palpable arteries of the wrist. If the arteries are occluded there is more than a 90 per cent chance that the condition is thrombo-angiitis obliterans or arteriosclerosis obliterans. In the fifth decade of life the necessity for distinguishing between these two conditions is, of course, more or less academic, since the problem of treatment is, with a few well defined exceptions, the same. The chief difficulty in diagnosing localized vascular disease of the extremities is in distinguishing the vasomotor or functional type from the organic type, particularly when the lesions are associated.

#### EDUCATION OF THE PATIENT

It is just as important to educate the patient who has thrombo-angiitis obliterans regarding the nature of his disease as it is to instruct the patient who has diabetes mellitus regarding his diet. This cannot be accomplished in a few hours or even in a few days. Patients must be cautioned to avoid trauma and undue exposure to cold. Patients should also be taught to avoid crushing or bruising the feet or toes, and they should be instructed in the proper care of scratches, cuts, cracks, blisters and burns. The slightest abrasion should be carefully treated and regarded as if it were a major injury. New shoes should be worn for only a half hour to an hour the first day, and considerable time should be spent in breaking in such shoes. Soft woolen stock-

ings should always be worn in cold weather. On many occasions simple abrasions produced by the wearing of new shoes have resulted in the formation of ulcers and in gangrene and amputation. Care of the toe nails is extremely important; it becomes more and more important as the blood supply to the digits decreases. Toe nails should be cut straight across, after being soaked in warm water, and they should be scrupulously but carefully cleaned. Corns, calluses and bunions should not be cut. Removal of ingrown toenails and minor operations on the toes in many cases have produced gangrene which in time has been followed by amputation. Such minor surgical procedures should be avoided except in rare instances and should then be performed only by a surgeon who is familiar with the problems involved in occlusive arterial disease.

Because of the poor blood supply to the feet, patients who have occlusive arterial disease may sustain injuries more readily than normal persons. They are also more susceptible to ill effects from exposure to cold. From the standpoint of cleanliness, the feet should be washed carefully and dried gently with a soft towel. Extreme care should be used in drying the skin between the toes. Brisk rubbing with a rough towel in many instances has produced ulcers. The occasional application to the feet and toes of a 50 per cent solution of alcohol is desirable, but this should not be used to excess. If the feet are excessively dry, or if the skin tends to crack or undergo scaling, hydrous wool fat or theobroma oil can be rubbed in gently to soften the skin. In numerous cases gangrene has been caused by the use of strong disinfectants, chemical compounds, ointments, corn cures and remedies for athlete's foot. It is unwise to use iodine, saponated solution of cresol, carbolated petrolatum or similar preparations as local disinfectants. Athlete's foot, which is a form of ringworm or trichophytosis, is frequently present in cases of thrombo-angiitis obliterans or arteriosclerosis obliterans and is usually worse in warm weather. This condition should receive appropriate care when it develops, as it is frequently the starting point of ulceration and gangrene between the toes. A safe method for treating athlete's foot is to soak the feet for a half hour each day in a 1:8,000 solution of potassium permanganate. This solution should be made up fresh for each soaking.

In spite of all the care which a patient may take, however, injuries to the toes and feet occasionally occur. When such a lesion develops, absolute rest in bed is indicated. In many a case in which gangrene has developed and the patient has lost an extremity he could perhaps have avoided such a calamity if he had taken the proper precautions early.

*Smoking.*—Mark Twain is reputed to have remarked that to stop smoking was the easiest thing he ever did, and he said he ought to know for he had done it a thousand times. Most patients who have thrombo-angiitis obliterans have had the same good intentions but have continued to smoke. Of the 948 patients, so far as I can determine only 106 stopped smoking. Eleven of these 106 expressed the opinion that the use of tobacco had been harmful to them. This phase of the problem is still being investigated.

About 50 per cent of those who stopped for varying periods resumed the habit, feeling that their symptoms were not improved after they had stopped. A rather large number, on the other hand, were convinced that smoking was the cause of their disease and said that they were greatly benefited after they stopped smoking.

Most of these gained weight, often from 15 to 20 pounds (7 to 9 Kg.) or more after they stopped smoking.

We at the clinic are of the firm conviction that all patients who have thrombo-angiitis obliterans should stop smoking. This, of course, brings up an interesting point as to the effects of tobacco on prognosis. A number of investigations have held that tobacco is the primary etiologic agent in the production of this disease, and yet, in this series, sixty-eight of the 948 patients had never used tobacco. Obviously the use of tobacco cannot be the cause of the disease, but it is evident, in the majority of cases, that excessive smoking does make the symptoms worse, although there are numerous exceptions even to this rule.

#### SUMMARY AND CONCLUSIONS

A total of 948 patients who had thrombo-angiitis obliterans were observed at the clinic from 1907 to 1937 inclusive. These patients came from every state in the Union except three and from ten foreign countries. More than twenty-eight different nationalities were represented. Two hundred and sixty-two (28 per cent) of the patients were Jews; 686 were Gentiles. The same fundamental pathologic process was present in all cases, and the signs and symptoms, as well as the clinical course of the disease, were strikingly similar. Twenty-one of the patients were women, the remaining 927 men; in other words, approximately 98 per cent of the patients were men. The mean age of the men was 41.8 years, of the women 38.8 years.

Of the 948 patients in the series 880 (93 per cent) were cigarette smokers. Of the 262 Jewish patients eighty-eight (33.6 per cent) underwent amputation, and of the 686 Gentile patients 313 (45.6 per cent) underwent amputation. Thus, 401 of the 948 patients underwent amputation either at the clinic or elsewhere. Eighty-five patients underwent bilateral amputation of the legs; sixteen of these patients were Jews and the remaining sixty-nine were Gentiles.

A study of amputations for three, five and ten year periods after the onset of the disease (table 4) indicates that approximately 70 per cent of patients will go for a period of three years from the onset without the necessity of amputation, whereas only 60 per cent will go for a period of five years and only 40 per cent for a period of ten years without being obliged to undergo amputation.

Perhaps the most important factors which determine whether a person who has thrombo-angiitis obliterans will continue to walk on two feet throughout life are early diagnosis and thorough education of the patient concerning the nature of his disease and the care of his extremities.

#### ABSTRACT OF DISCUSSION

DR. F. E. BOLLAERT, East Moline, Ill.: May I inquire about the recent treatment by suction pressure as well as the hyperemia treatment of these cases?

DR. BAYARD T. HORTON, Rochester, Minn.: The alternate suction and pressure apparatus is being used rather widely and we have used it for a number of years. I do not believe that we get any better results from the use of this machine than we can get from other simpler methods. I prefer the use of the Saunders bed to this alternate suction and pressure apparatus. With the use of the Saunders bed the patient must be kept in an environmental temperature of 82 degrees or above because one cannot get rid of vasospasm, particularly in the feet, unless the environmental temperature is at or above that level.

## THE SURGICAL PATHOLOGY OF NASAL SINUSITIS

HERMAN SEMENOV, M.D.

LOS ANGELES

The first essential in the treatment of nasal sinusitis is an exact differential diagnosis of the surgical and nonsurgical types of disease condition present in the lining membranes. A lack of precise histopathologic knowledge in the past has led to the indiscriminate removal of tissues essential to the physiology of the nose and accessory sinuses. As every one knows, this has been attended by a striking array of contradictory results.

The purpose of this report is to recount in as much detail as possible the known types of sinusitis, the effects of allergy on the course of the sinus disease, the separation of reversible inflammatory from irreversible degenerative changes, and the character of the lining that forms after radical operations. The chief desideratum is a working principle which will delineate the types of disease present in every case and indicate the most appropriate treatment for each. The method of choice, selected from the several methods of treatment at hand, should completely remove the underlying disorder and most nearly conserve the normal functions of the nose and accessory sinuses.

#### MATERIAL AND METHODS

In this undertaking the histology and physiology of the sinuses were carefully reviewed and numerous normal membranes were taken from cadavers for measurement with the micrometer. The surgical specimens were measured at the principal point of disease and the results arbitrarily correlated with the exudative, proliferative and degenerative changes noted microscopically.

The material for the present report embraces more than a thousand sections collected and examined during the past ten years. The membranes were removed in one piece by careful subperiosteal dissection (Caldwell-Luc, transantral and external frontal ethmoidal operations), mounted on cardboard supports or stretched over wads of cotton and fixed in 10 per cent solution of formaldehyde (fig. 1). They were sectioned by the paraffin method, stained as a routine with hematoxylin and eosin, occasionally with other methods of special staining, and in numerous instances with the Gram bacterial stain. The bacteriology of 400 sinuses was investigated by making swabs at the time of operation. Tissue cultures were made from 120 sinuses by grinding the membranes in sterile sand.

#### INCIDENCE OF ALLERGY IN SURGICAL CASES

1. *Nonallergic Cases* (47.6 per cent).—These include cases with a negative history of hay fever or asthma, absence of characteristic rhinologic signs (vasomotor rhinitis, bluish appearance of the turbinates) and lack of eosinophilia in the histologic preparations.

Owing to lack of space, this article has been abbreviated for publication in *THE JOURNAL*. The complete article appears in the author's reprints.

Read before the Section on Laryngology, Otology and Rhinology at the Eighty-Ninth Annual Session of the American Medical Association, San Francisco, June 17, 1938.

This work was started in 1928 under the facilities of the Nebble Wiley Jones Fellowship in Pathology in the Department of Pathology of the University of Oregon Medical School in collaboration with Dr. Frank B. Ristner.

2. *Manifest Allergic Cases* (17 per cent).—These include cases with history, symptoms or signs of hay fever or asthma, suggestive bluish appearance of the turbinates, polypoid degeneration of the nasal mucosa and microscopic appearance of tissue eosinophilia, edema of the submucosa, hyaline degeneration of the basement membrane and mucoid degeneration of the overlying epithelium.

3. *Equivocal Allergic Cases* (35.4 per cent).—This group includes a large number of latent allergic conditions and a more or less variable number of pseudo-allergic specimens in which the history was uncertain, vague or incomplete but in which microscopic examination showed tissue eosinophilia in association with one or more other histopathologic signs sufficient to warrant a presumptive diagnosis of latent allergy, if one were so inclined.

Nearly 52.4 per cent of the surgical cases presented histopathologic signs which suggested the possibility

dence of cysts and abscesses (50 per cent) was even greater in the cases in which polypoid degeneration developed (thickening 3 to 10 mm. or more). Bacteria were demonstrated by culture of the fluid in nearly half of the serous cysts. Typical cases with reports of the bacteriology and pathologic histology of nonpurulent sinusitis and several interesting cases of latent sinus infection without clinical signs of suppuration have been described in previous publications.<sup>2</sup>

#### BACTERIOPATHOLOGY

Mixed infections of two or more organisms occurred in 80 per cent of the cases of chronic sinusitis. Streptococci predominated in both the swabs and the tissue cultures. They were present in 94.5 per cent of the cases. Staphylococci appeared in 70 per cent. Sixty-eight per cent of the chronic sinuses contained alpha and beta hemolytic streptococci, 14 per cent the non-hemolytic *Streptococcus viridans* (alpha), and 18 per cent the nonhemolytic streptococcus (gamma). In addition to and frequently in combination with the streptococci the chronic sinuses contained staphylococci, *Micrococcus catarrhalis*, pneumococci, Friedländer's

Fig. 1.—A, removal of specimen of sinus; B, method of mounting on cotton; C, specimen showing large serous mesothelial cyst.

of an underlying allergy. Of this number at least 17 per cent were definitely allergic. More than 70 per cent of the obviously allergic cases presented superimposed suppurating infection.

Purulent sinusitis with exudate in the nose, diagnostic puncture (cytologic examination) and histologic

bacilli, influenza bacilli, colon bacilli, diphtheroids and Streptothrix.

The virulence of the streptococci was tested in twenty rabbits and found to be pathogenic in seventeen. Various lesions were produced in the brain, heart, liver, kidneys, arteries and articular joints. Experimental arteritis and arteriosclerosis were produced in five rabbits with the hemolytic *Streptococcus anginosus* from a case of chronic sphenoiditis and large inguinal abscesses and myocardial and hepatic changes in two monkeys that were inoculated with the nonhemolytic *Streptococcus mitis* from a chronically infected antrum.<sup>3</sup>

A pure culture containing only one type of organism was found in only 20 per cent of the sinuses. Beta hemolytic streptococci appeared most frequently in purulent sinusitis. Staphylococci, especially the hemolytic type, also produced marked suppuration.

#### NORMAL HISTOLOGY OF THE MUCOPERIOSTEUM OF THE SINUSES

The sinus lining is less robust, less vascular and less glandular than the schneiderian membrane (fig. 2). Erectile tissue is lacking, the stroma is quite weak and rudimentary, and the entire lining is much thinner than the nasal mucous membrane.

sections was present in 72 per cent of all the cases. Nonpurulent sinusitis (hyperplastic, polypoid and cystic) was present in the remaining 28 per cent.

Nonpurulent hyperplastic, polypoid and cystic degeneration of the sinuses may arise as a consequence of either a suppurative process which has subsided or a nonsuppurative allergic process. Abscesses formed in 10 per cent and cysts in 33 per cent of the hyperplastic sinus membranes (thickening 1 to 2 mm.). The inci-

The mucoperiosteum is composed of a single layer of pseudostratified ciliated columnar epithelium, which rests on a delicate basement membrane, and two layers of connective tissue: (1) a loose subepithelial areolar layer and (2) a compact periosteal layer (fig. 3 *B*). Under normal conditions there are very few goblet cells in the epithelium and no signs of edema or round cell infiltration in the submucosa.

Total.....	81	

The normal sinus membrane is very thin, about 0.1 mm. in thickness, and may be compared to the membrana tympani, which is also 0.1 mm. in thickness.

The loose subepithelial layer has wide tissue spaces and usually becomes extremely edematous. The edema frequently ruptures the fibrils of areolar connective tissue and leads to the formation of mesothelial cysts. There is an astonishing degree of variation in the histologic structure of the subepithelial stroma. Some membranes are composed entirely of areolar tissue and these are prone to develop marked degenerative changes after trivial sinusitis; others are composed of a tougher periosteal type of stroma and successfully resist infection for many years (fig. 3).

The glands in the mucous membrane of the sinuses are relatively scarce. In the ethmoidal, sphenoidal and frontal sinuses submucous glands appear only in the neighborhood of the ostia.

In general the membrane of the maxillary sinus differs from that of the ethmoidal, the sphenoidal and the

ing of the antrum is loosely attached to the superior, posterior and lateral walls by delicate strands of connective tissue. The frontal membrane (pneumatization quite late in life) appears to be the most rudimentary of all the paranasal sinuses.

There are very few blood vessels in the mucosa of the sinuses and the circulation seems relatively poor.

Fig. 3.—A, mucosa composed entirely of loose areolar tissue with rudimentary periosteum; B, normal mucoperiosteal arrangement; C, dense fibrous submucosa with very little loose tissue.

This may in part account for a slower rate of healing and a higher incidence of degenerative changes.

#### HISTOPATHOLOGY OF SINUSITIS

Increase in thickness of the membrane is caused partly by the cellular infiltration, partly by the edema of the connective tissue and partly by the proliferation of fibroblasts, which generally give the stroma a myxomatous appearance.

**Cellular Exudation.**—The leukocytic sequence in acute inflammation consists of an initial polymorphonuclear infiltration which is followed immediately by lymphocytes, eosinophils and mononuclear macrophages. All types of cells may be present in the subepithelial tissues within a period of fifty hours after the onset of the inflammatory reaction. The polymorphonuclear cells pass through the epithelium in great numbers and predominate in the pus that forms on the surface of the membranes. The lymphocytes and

TABLE 3.—Thickness of Mucous Membranes of Sinuses

plasma cells are inclined to remain within the tissues and for this reason predominate in the submucosal picture.

In 1927 Finck<sup>5</sup> noted the presence of eosinophilic infiltration in the nasal mucosa of allergic patients. In 1929 Kistner and I<sup>6</sup> confirmed this finding in the sinuses and with a few exceptions during the past ten years have found eosinophilic infiltration constantly present in allergic membranes. Numerous investiga-

frontal only on its medial walls, where the structure is more complex owing to a rich supply of blood vessels and glands, which may be attributed to the earlier embryonic history of this part (paleosinus) in the development of pneumatization. The mucosa of the lateral wall of the antrum (neosinus) is poorly developed and resembles the frontal sinus in many respects. The lin-

5. Finck, H. P.: Tissue Changes in the Nasal Mucosa, *Laryngoscope* 37: 783-797 (Nov.) 1927.

6. Kistner, F. B., and Semenov, Herman: Pathology of Sinusitis, *Tr. Pacific Coast Oto-Ophthalm. Soc.*, 1929; *Ann. Otol., Rhin. & Laryng.* 38: 978 (Dec.) 1929.

tors, notably Hansel,<sup>7</sup> have studied the presence of eosinophils in smears of the nasal discharge and it is now a well established routine diagnostic method.

**Mucoid Exudate.**—The mucous membranes of the sinuses, as their name indicates, are moistened by a mucus-containing secretion. Under normal conditions only a small quantity of a limpid mucus is formed, but with the advent of irritation a more viscid secretion

Fig. 4.—A, goblet cells and mucoid degeneration in catarrhal sinusitis; B, hyperplastic ciliated epithelium in purulent sinusitis; C, epithelial metaplasia with leukocytic emigration.

appears. Most of the viscid mucus found in the sinuses is actually formed by mucoid degeneration of the surface epithelium.

Mucoid degeneration (fig. 4 A) is a very common process in the epithelium of the sinuses. It is manifest by the appearance of an abnormal number of goblet cells. The cilia are lost under these conditions and wide areas of sloughing epithelium, presenting only a remnant of basal cells, are frequently seen in allergic sinuses. This is one of the reasons why allergic sinuses are so frequently infected. In purulent sinusitis some areas show ciliated columnar cells, others hyperplasia (fig. 4 B), metaplasia (fig. 4 C) and focal necrosis (fig. 5). Hypertrophy and hyperplasia appear as defense reactions after chronic mucoid degeneration runs a protracted course.

Fig. 5.—Chronic purulent sinusitis with infection of the glands, edema, infiltration and necrosis of epithelium and cystic dilatation.

**Proliferative Changes.**—Hyperplasia is present when there is an increase in the number of cellular elements. Hyperplastic processes in all cases produce a tissue similar to that of the original part; hyperplasia of the epithelium gives rise to new epithelial cells, that of the glands to new gland cells, that of the connective tissue to new connective tissue cells, and so on. Hyperplasia of the stroma clearly follows acute inflammatory processes and bears the same relation to injury that

the cicatrix and healing wound do to the granulation tissue from which they spring.

Proliferation of the connective tissue produces the greater part of the irreversible thickening of the sinus membranes (fig. 6). There is an increase in the number of fibroblasts and spindle and stellate cells. The subepithelial areolar layer tends to undergo polypoid degeneration (edema and a soft myxomatous tissue), but the more compact periosteal layer is more resistant to edema and infiltration. The periosteal portion tends to thicken and become more or less tough and fibrous during the course of chronic sinusitis.

The pathologic changes in hyperplastic sinusitis may be circumscribed or diffuse, involving either certain parts or the entire lining of the sinuses (figs. 6 to 9). The mild form of hyperplastic sinusitis tends to run a slow, insidious course with remissions and exacerbations. The exudative and edematous changes are

reversible and may subside completely after the exciting causes (allergy or infection) are removed, or they may continue on for weeks, months or even years without giving rise to symptoms. In the latent form of hyperplastic sinusitis, washings from the antrum usually contain numerous degenerating epithelial cells on cytologic examination.

DEGENERATIVE CHANGES

1. **Retention Cysts.**—Obstruction of the gland ducts by leukocytic infiltration (fig. 5) initiates the formation of retention cysts, and as each acinus becomes cystic it encroaches on the adjacent glands; eventually the dilated tubules rupture into one another. The interior of a retention cyst is lined with epithelium in various stages of degeneration. Sometimes there are areas devoid of epithelium bordering on areas of flattened cells which gradually pass over into columnar cells, and finally one may find mucous or goblet cells. It is probable that the epithelial variations represent stages in the cystic evolution. Retention cysts contain a thick mucoid material which sometimes is mixed with concentric deposits of epithelial debris and leukocytes.

7. Hansel, F. K.: Allergy of the Nose and Paranasal Sinuses, St. Louis, C. V. Mosby Company, 1936.

2. *Mesothelial Cysts*.—When the tissue spaces of the loose areolar stroma become extremely edematous, they frequently rupture and form large cystic cavities. These cysts have no epithelial lining. They are usually thin walled and in the absence of suppuration are filled with a clear amber fluid (fig. 1 C).

Cystic degeneration appeared in one third of all the cases of chronic sinusitis. It was greater in the mucous membranes that were more than 2 mm. in thickness (50 per cent), especially in the allergic specimens. Normal glands were found in only 15 per cent and cystic dilatation with abscess formation in 85 per cent of the manifest allergic cases. Abscesses appeared in from 5 to 15 per cent of the purulent sinuses.

3. *Polypoid Degeneration*.—Polypoid degeneration, whether it is bacterial, allergic, catarrhal or suppurative, is always characterized by great edema, which may be attributed to impaired circulation, abnormal capillary permeability and lymphatic obstruction in a delicate stroma. There are many other factors responsible for this condition, but the loose histologic structure of the mucosa of the sinuses and the presence of chronic edema (allergy or chronic infection) are the evident predisposing factors.

Polyps consist of a water-logged myxomatous connective tissue in both the nose and the paranasal sinuses. Eosinophilia was found in more than two thirds of the

Fig. 6.—A, normal thickness of lining; B, hyperplastic sphenoidal membrane, ten times normal thickness. Figures 6, 7, 8 and 9 are reduced from photomicrographs with a magnification of ten diameters.

polypoid specimens. These cases were considered allergic; no evidence of eosinophilia was found in one third of the cases and the pathologic condition was considered nonallergic.

In a recent publication Kern and Schenck<sup>8</sup> stated that allergy is a constant factor in the etiology of nasal polypi. They believe that nearly 100 per cent of mucous polyps are allergic in origin. Walsh and Lindsay<sup>9</sup> in a well controlled investigation of seventy-five cases of nasal polyposis found that some were associated with allergy and others with nonallergic infection of the nasal accessory sinuses. The nonallergic polypi are usually unilateral, and removal is followed by better results than removal of allergic polypi, which are frequently bilateral.

Polypoid degeneration throws the surface of the mucous membrane into crypts and pockets, which retain much infection and interfere with ciliary action. Non-allergic polypoid sinusitis demonstrating mesothelial cystic degeneration may be seen in figure 7. Allergic sinusitis with extensive formation of mucus and marked polypoid edema of the loose areolar tissue may be seen in figure 8. Marked polypoid degeneration with a large mucous cyst and a large mesothelial cyst may be seen in figure 9. This specimen is from a patient with

allergy and demonstrates the great tendency of allergic sinusitis to develop into pronounced degenerative changes.

Choanal polyps sometimes form in the sinuses, especially in the antrum, and extrude through the ostium into the nasopharynx. The origin of these polyps is frequently on the lateral wall of the antrum (fig. 10). I have often wondered why this should be so; one would ordinarily expect polypi to begin near the ostium

Fig. 7.—Polypoid degeneration in chronic purulent sinusitis, nonallergic. Thickening from ten to forty times normal.

where the greatest amount of irritation and discharge is to be seen. The answer lies, I believe, in the histology and embryology of the antrum. The lateral portion, as has already been stated, is extremely thin, changes quite late in life and belongs to the rudimentary neosinus. It is therefore quite delicate and subject to greater degenerative changes, since the blood supply and lymphatic drainage of this region are so vulnerable.

According to André,<sup>10</sup> Grunwald<sup>11</sup> and Mullin and Ryder,<sup>12</sup> the lymphatic channels lie in the membranes and follow a circuitous course to the ostium. Obstructive processes, either vasomotor, allergic, infiltrative or inflammatory, have many opportunities to interfere with this extended line of communication and may easily give rise to back pressure, chronic hydrops mucosae and polypoid swelling on the lateral wall of the antrum.

Considerable absorption of bone and osteoporosis accompany polypoid degeneration. Every one is famil-

Fig. 8.—Polypoid allergic sinusitis from fifteen to fifty times normal thickness.

iar with osteoporosis of the middle turbinate in polypoid degeneration of this structure. I have several times seen extreme absorption in the canine fossa as a result of the chronic hyperemia and stasis associated with polypoid degeneration within the antrum. A pyogenic

process seldom creates this condition. As a matter of fact, pyogenic inflammation often leads to formation of new bone and fibrosis.

#### REGENERATION AND HEALING OF THE MUCOUS MEMBRANE OF THE SINUSES

There are few, if any, references in the available literature to the microscopic appearance of the mucous membranes of the sinuses after inflammation has subsided and complete healing has resulted. The question frequently arises Does sinusitis ever heal completely and what happens when it heals without operation? These questions may be answered by the following case:

A man aged 50 had apparently recovered without surgical treatment from a chronic mucopurulent sinusitis of twenty-five years' duration. For a period of four years he was free from colds, nasal discharge and sinusal symptoms. X-ray examination of the sinuses revealed definite thickening and blurring of the antrums, ethmoids and sphenoids. The mucous membranes were removed, sectioned and found to be many times the normal thickness. When examined under the microscope, the epithelium was perfectly normal. The submucous connective tissue, instead of being loose and areolar, was thick and fibrous (fig. 3C).

Fig. 9.—Polypoid and cystic degeneration in allergic sinusitis, showing mesothelial cyst and retention cyst. From fifty to seventy times the normal thickness.

The stroma was fully 2 mm. thick. There were no signs of edema, inflammation or degeneration. The glands were compact and surrounded by firm connective tissue.

This interesting mucoperiosteum apparently became tougher and stronger as the years went on. Similar changes have been noted in the ethmoidal, sphenoidal and maxillary membranes in several other cases. Healing by fibrosis is a desirable end result as far as the sinuses are concerned.

*Postoperative Repair and Regeneration of Sinus Lining.*—The blood clot on the denuded osseous wall gradually organizes and becomes converted into scar tissue. Epithelium spreads from the bordering nasal mucosa and gradually covers the surface of the scar tissue.

In previous publications Kistner and I<sup>13</sup> called attention to the presence of scar tissue and the variability of the epithelial regeneration, especially the cilia. This does not mean that the cilia are absent altogether, for we have always maintained that healing varies from place to place and from person to person and there is no reason why it should not produce perfectly normal epithelium in some cases. From a practical point of view, however, the postoperative membrane is a poor

substitute for the original mucous membrane of the normal sinus. Hilding's<sup>14</sup> physiologic experiments in the frontal sinuses of dogs demonstrate the existence of impaired ciliary function in those areas in which the mucous membrane has been removed and permitted to regenerate. This postoperative condition of the lining, on the other hand, is much better than a pathologic sinus full of polypi, cysts and abscesses, but one should not justify radical surgery on the assumption that the postoperative condition of the tissue is normal sinus mucoperiosteum.

#### COMMENT

Anatomic obstructions, such as deflections of the nasal septum, concha bullosa and similar abnormalities, are predisposing factors in the etiology of chronic sinusitis. Repeated attacks of nasal congestion with thickening and polypoid degeneration are frequently due to an allergic constitution. Allergy is a predisposing factor in nearly half of the cases of sinusitis. Trauma, epidemic colds and bacterial invasion by extension from neighboring foci of infection such as dental abscesses, oro-antral fistulas and osteomyelitis of the jaw have long been known to be exciting factors.

The treatment of chronic sinusitis may terminate successfully after the offending obstructions and hypersensitiveness to extrinsic allergens have been corrected.

Exudative changes are frequently reversible when ventilation and drainage are established. Degenerative changes with pronounced thickening of the mucous membrane rarely respond to simple drainage and usually require radical surgery of the sinuses (fig. 10B). A subacute mucopurulent sinusitis often responds to the Proetz displacement method of irrigation and suction. A suppurative infection, however, with empyema of the sinuses may require surgical intervention before adequate drainage is obtained. Chronic purulent sinusitis that fails to respond to conservative methods of drainage invariably shows deep seated infection of the glands and cystic degeneration of the submucosa (fig. 5).

Nonpurulent hyperplastic sinusitis rarely requires surgical intervention. Nearly two thirds of the cases are due to allergy, especially when a bilateral process is present. The allergic constitution predisposes one to pansinusitis and degenerative changes of the mucous membrane of the entire upper respiratory tract. For this reason it is well to treat the underlying allergic condition before serious consideration is given to surgical intervention. Purulent sinusitis in an allergic individual should be treated simply as a local problem of drainage. The results, however, are not as brilliant as in nonallergic persons. Healing is more sluggish and polypoid edema tends to appear even in the granulation tissue. With this in mind I believe that the statistics of the future will show a higher incidence of cured sinusitis once the allergic conditions are recognized as such and treated with the same consideration that is afforded syphilitic and tuberculous conditions.

#### SUMMARY

1. The microscopic changes of the sinusal mucoperiosteum in several hundred surgical specimens show that thickening in excess of 2 mm. is associated with deep seated degenerative changes in 50 per cent of the cases.

13. Semenov, Herman, and Kistner, F. B.: Repair in the Paranasal Sinuses of Man Following Removal of Mucous Membrane Lining, *Proc. Soc. Exper. Biol. & Med.* 27: 322 (Jan.) 1930. Kistner, footnote 2, second reference.

14. Hilding, Anderson: Experimental Surgery of the Nose and Sinuses: II. Gross Results Following the Removal of the Intersinus Septum and of Strips of Mucous Membrane from the Frontal Sinus of the Dog. *Arch. Otolaryng.* 17: 321 (March) 1933.

2. Purulent sinusitis constitutes 72 per cent of the cases. Nonpurulent hyperplastic polypoid and cystic degeneration constitutes 28 per cent of the cases.

3. Degeneration of the mucous membrane of the sinuses may be explained in part by the rudimentary microscopic structure of the stroma. A preponderance of loose areolar tissue favors the formation of mesothelial cysts and polypoid degeneration. Membranes of the sinuses endowed with a more fibrous periosteal type of stroma are resistant to the same pathologic processes. The healing power in such a membrane is shown in the case described as it appeared after twenty-five years of mucopurulent sinusitis.

4. Manifest allergic sinusitis occurs in 17 per cent. Nonallergic inflammation of the sinuses as determined by a careful history and examination of the patient and histologic preparations appeared in 47.6 per cent of the cases.

5. The allergic membrane is prone to infection and resistant to treatment. Degenerative changes are greater in allergic sinuses. Hyperplastic sinusitis, especially the

tive changes (abscesses, fibrosis, myxomatous degeneration and so on) is too high. I wonder whether this which we are supposed to accept as allergy might not better be called a characteristic reaction of some people to insult. If this insult is from foreign protein to which they are sensitive, one has manifest allergy. But this reaction may appear to infection or even to chemical insults, and the reason some individuals so react is as yet unknown. At any rate Dr. Semenov's facts show that the rhinologist should not in the presence of this "equivocal allergy" abandon the field. He should study his case more intensively, review the history and every factor involved with meticulous care, and frequently ask for the help of the allergist; but he should not abdicate and should realize that even complete and extensive surgical operation may be necessary in obtaining results. Pathologic classifications cannot be dogmatically applied to individual cases.

DR. RAYMOND O. DART, San Francisco: Dr. Semenov's comprehensive research into the anatomy of the paranasal sinuses is of practical value to the general pathologist. In the aggregate, it is probable that a greater number of rhinologic specimens are examined by general pathologists than by specialists in the field of rhinology. The general pathologist looks to the specialist for the researches which pave the way for him

to make more accurate diagnoses in his routine work. In the available literature on the subject, little is found on the normal anatomy of the paranasal sinuses, and the classifications of the various pathologic processes found in these membranes are varied and confusing. The recognition of allergy as the basic pathologic condition in a large proportion of cases has added to the diagnostic difficulties of the general pathologist. It is not surprising, therefore, to find conflicting reports on the results of the treatment of these cases. Dr. Semenov has defined the limits of the normal anatomy of the paranasal membranes and outlined a workable classification of the various pathologic processes. It is interesting to

Fig. 10.—A, polyps arising in the antrum attached to the lateral wall and projecting through the ostium into the nasal cavity; B, multiple cystic abscesses in right and left maxillary sinus from a patient with chronic purulent degenerative allergic sinusitis.

bilateral type, is allergic in 70 per cent of the nonpurulent cases.

6. Tissue cultures reveal a preponderance of streptococci and staphylococci in chronic sinusitis, mixed infection being present in 80 per cent.

7. Exudative sinusitis usually responds to conservative treatment. Degenerative changes which are irreversible in character require radical treatment.

8. Postoperative healing in the paranasal cavities is accomplished by the formation of a dense layer of white fibrous connective tissue which epithelizes by an ingrowth of nasal mucosa.

#### ABSTRACT OF DISCUSSION

DR. ROY F. NELSON, Oakland, Calif.: Pathology is a basic science. I fear I am becoming hypersensitive to the word "allergy." I have a healthy skepticism, doubting whether it is really known what is meant by that word. I know that allergy exists clinically, usually caused by extrinsic foreign proteins and amenable to treatment. However, sometimes "allergy" is used too loosely and has little meaning except "different" or not otherwise understood. Dr. Semenov's classification of "equivocal allergy" is good, but might one not better find some other term altogether? I doubt that eosinophilia and polyposis are necessarily diagnostic of allergy in the accepted clinical sense. Fifty per cent of "equivocal allergic" manifestations in surgical cases is entirely too high. The incidence of frankly degenera-

note that in 35.4 per cent of the author's cases histopathologic conditions suggestive of allergy could not be correlated with clinical history or symptoms. This, together with conflicting reports of other investigators concerning the incidence of allergy and its relation to sinusitis, would indicate that there is need for further and more comprehensive work on this phase of the subject. It is suggested that further studies in this field might be undertaken in a cooperative effort by rhinologists by means of a registry of rhinologic pathology. The splendid results obtained from existing registries are well known. The purpose of most registries has been the study of cancer. Other diseases than cancer might well be made the subject of a comprehensive registry study. A start in this direction was made by the American Academy of Ophthalmology and Otolaryngology when it established the registry for the Section on Laryngology, Otology and Rhinology. Selected cases from this registry were used to prepare the loan sets of otolaryngic pathology now available to members of the academy who are preparing for the examinations of the board. An active registry study of the subject of sinusitis would undoubtedly result in greater understanding of the underlying pathologic principles with consequent improvement in diagnoses and methods of treatment.

## Clinical Notes, Suggestions and New Instruments

### EXTREME OBESITY FOLLOWED BY THERAPEUTIC REDUCTION OF TWO HUNDRED AND THIRTY-NINE POUNDS

JAMES J. SHORT, M.D., NEW YORK  
Associate Clinical Professor of Medicine, New York Post-Graduate  
Medical School of Columbia University

The question of how much or at what rate weight may be removed safely is a moot one. From 395½ pounds (180 Kg.), the patient whose case is reported here reached a low weight of 156½ pounds (71 Kg.) in twenty months, with progressive improvement in health throughout the period and subsequently.

#### REPORT OF CASE

L. G., a woman aged 32, Russian, a housewife, applied to the Obesity Clinic for weight reduction on March 22, 1935. She had always been overweight. At 17, when she was married, she weighed 260 pounds (118 Kg.). There had been no change in her mode of living. She considered that her optimum weight

Fig. 1.—Patient when she weighed 402 pounds.

subjectively had been 195 pounds (88.5 Kg.); her maximum weight had been 402 pounds (182.3 Kg.). She slept from eight to ten hours a night, used little tobacco and no alcohol, and had a very good appetite. There were no gastrointestinal symptoms nor any relative to the extremities, such as varicose veins, fallen arches, painful knees or edema. The menses had been irregular since onset, with the exception of the three months just prior to admission, when they followed a twenty-eight day cycle, each period lasting about two and a half days. She had suffered from psoriasis since the age of 8 years.

Her father was of normal weight. Her mother weighed approximately 300 pounds (136 Kg.) and suffered from diabetes. Her brother had weighed 230 pounds (104 Kg.) maximum but at that time weighed 185 pounds (83.9 Kg.). One sister was

obese at 185 pounds. There was no history of hypertension or of cerebral accidents. Two sisters and one brother had died in infancy.

Her height was 63 inches (160 cm.), weight 395½ pounds (the estimated normal was 145 pounds [65.8 Kg.]). The skin showed rather extensive psoriasis, the teeth showed evidence of mild pyorrhea and the tonsils were hypertrophied and cryptic. The arteries were not unduly thickened and the blood pressure was 160 systolic, 120 diastolic. There were a few moist rales at the base of the right lung. The size and contour of the heart were not determined and the abdominal organs were not palpated because of extreme obesity. The physical examination was otherwise essentially negative.

The urine was normal. Dextrose tolerance tests (done by giving the patient 100 Gm. of dextrose in the postabsorptive state) at the fasting and one and two hour periods were respectively 113, 160 and 154 mg. per hundred cubic centimeters of blood March 28, 1935, and 80, 125 and 125 mg. July 14, 1936. At the time of the second dextrose tolerance test, definite hypoglycemic symptoms had become manifest. The urine sugar was negative at all times. Basal metabolic rates are shown in table 1. Blood urea nitrogen was 13.5 mg. and nonprotein nitrogen 32 mg. per hundred cubic centimeters.

This was considered a case of simple obesity, the result of prolonged overnutrition. There were no manifestations to indicate an endocrine etiology.

For treatment she was given a diet, with occasional variations, of approximately 600 calories, which consisted of 35 Gm. of carbohydrate, 70 Gm. of protein and 20 Gm. of fat. Thyroid extract was given in a dose of 3 grains (0.2 Gm.) daily after the second basal metabolism test of April 9, 1936. This was varied from time to time according to indications. The patient followed orders faithfully throughout the entire period from March 22, 1935, to Nov. 17,

Fig. 2.—After course of treatment when the patient weighed 186½ pounds.

Fig. 3.—Excess skin removed by operation, measuring 24¾ by 12¼ inches.

1936, at which time she weighed 156½ pounds without clothing. A record of her weight losses is shown in figure 4 and table 2.

September 29 she was referred to Dr. Gustave Aufricht of the department of surgery for the removal of excess skin and subcutaneous tissue. At that time her weight was 177½ pounds (80.5 Kg.). Over the abdomen there was a rather large apron

of skin, which was removed by operation October 27 and weighed 5½ pounds (2.5 Kg.). She made a good recovery and was discharged November 17.

## COMMENT

The patient's health remained excellent throughout the entire period of reduction. At no time did she complain of hunger or weakness. There was a moderate improvement in the

psoriasis, and the skin showed remarkable adaptability to the smaller proportions. At a weight of 156½ pounds she was in excellent health and spirits, and there was little, when she was clothed, to indicate that she had ever been obese.

During the first months of the reduction period the patient's average loss was 12 pounds (5.4 Kg.) a month. In my experience most patients show an average loss of weight over prolonged periods of 10 pounds (4.5 Kg.) a month.

This case would indicate that there is no limit in the extent to which excess weight may be removed by submaintenance diets, provided such diets contain adequate protein, minerals and vitamins, together with moderate amounts of carbohydrate. Fats may be minimal. To insure sufficient vitamins, these are often added, as such, in concentrated form. Dairy products, such as skim milk and cottage cheese, are valuable in providing adequate calcium and phosphorus. Reductions of from 10 to 20 pounds a month over considerable periods have not been attended by any untoward symptoms in my experience. These observations are entirely in accordance with those of Evans and Strang,<sup>1</sup> who advocate rapid reduction of weight on low calory diets.

An important feature of this case was the high initial total heat production. This, since fat cells themselves are largely inert,<sup>2</sup> in persons who are overweight has the same significance as the "basal" metabolism in those of normal weight and is of far greater importance in indicating the energy exchange of the nonfatty energy-producing tissues of the body.

The figure used to indicate the total heat production is a percentage above or below that which would be produced if the individual were of normal weight (therefore of normal surface area) and had a normal rate of heat production. It is obtained by determining the ideal weight for the individual and from this and the height combined the normal surface area in square meters. This is then multiplied by the calories,

per square meter per hour, that the person should have; i. e., the normal basal metabolism figure. The resultant figure represents the total calories per hour that the person should produce at ideal weight. A comparison with the actual caloric output per hour gives the percentage above or below the normal. This is identical with the current method of expressing the "basal" metabolism, which is also given as a percentage above or below an average normal.

No confusion need be experienced in understanding these two methods of expression if it is remembered that "basal" metabolism relates to heat production under standard conditions per unit of body surface and that total heat production relates to the body as a whole. This important distinction has been too generally ignored. Clinicians have often assumed in the study of overweight that, since the "basal" metabolism is reported normal, the patient's rate of metabolism is also normal. The opposite is actually the case, since the total energy output of the obese is almost invariably too high. The extent to which the metabolism rises depends on the degree of overweight and the consequent increase of surface area. The increase of total heat production, therefore, is in direct proportion to the increase in surface area, provided the "basal" rate remains constant.

In the case under discussion, the total heat production originally was 56 per cent above normal. This might well be compared to a case of normal weight with hyperthyroidism, in which the "basal" metabolism is +56 per cent. Many overweight patients exhibit symptoms similar to hyperthyroidism—hypertension, tachycardia, stimulation of the sympathetic nervous system and diminished dextrose tolerance. This, in my opinion and in that of other observers,<sup>3</sup> can be directly related to the increased metabolism.

The return of the total heat production to normal limits with restoration to ideal weight, as seen in this case, is characteristic. Coincidentally there was a marked subjective improvement throughout the reduction period and an improvement in the dextrose tolerance until symptoms of hypoglycemia were experienced.

To counteract the characteristic decline of the metabolic rate resulting from submaintenance diets (presumably due to a loss of the specific dynamic action of foodstuffs and possibly other factors) I employ thyroid extract in adequate dosage. This dosage has been controlled in a considerable number of cases

Fig. 4.—Effect of low calory diets and thyroid therapy on weight, surface area, basal metabolism and total heat production.

by repeated determinations of the metabolic rate. Thyroid has been consistently used in the clinic to offset the falling rate of metabolism resulting from reducing diets and to maintain a satisfactory weight loss. Though not well tolerated early for the obvious reason of an increased metabolism, it is well tolerated later, after the effect of the reducing diet has manifested itself.

**Special Clinical Article****GASTRIC HEMORRHAGE**

CLINICAL LECTURE AT SAN FRANCISCO SESSION

DAMON B. PFEIFFER, M.D.

PHILADELPHIA

Gastric hemorrhage is a dramatic event. When a person vomits bright red blood or passes a large tarry stool and when in either event he experiences the sickening weakness which accompanies hemorrhage, he usually knows what to do. He calls his doctor. Until a few years ago the doctor, with rare exceptions, thought he also knew what to do. He instituted treatment based on starvation and sedation.

I propose to discuss the problem of gastric hemorrhage from the standpoint of treatment, and as a surgeon I shall confine my discussion to the type of hemorrhage for which the value of surgical intervention is becoming recognized, namely bleeding peptic ulcer. Peptic ulcer, according to Bulmer,<sup>1</sup> causes 89 per cent of acute hemorrhages from the upper part of the intestinal tract, 5.3 per cent of such hemorrhages being caused by esophageal varices and 1.5 per cent by gastric carcinoma. Owen,<sup>2</sup> in studying 137 cases of gross and massive hemorrhage from the intestinal tract at the Philadelphia General Hospital, found that 68 per cent of the hemorrhages were caused by peptic ulcer, 25 per cent by gastric carcinoma and 6 per cent by varices or carcinoma of the esophagus.

That bleeding ulcers give rise to the majority of gastric hemorrhages and hemorrhages from the upper part of the intestinal tract is clear. That the differential diagnosis between peptic ulcer, carcinoma of the stomach, gastritis and the varices of cirrhosis or splenomegaly can be far from simple is perhaps not so well appreciated. It is important, nevertheless, to establish the diagnosis at the earliest possible moment. To discuss differential diagnosis, however, is beside the purpose of this paper.

The problem of treatment arises at once and, like the problem of diagnosis, it is far from simple. Early feeding, as advocated by Meulengracht,<sup>3</sup> the massive drip transfusion<sup>4</sup> and the aluminum hydroxide drip,<sup>5</sup> all relatively recent innovations, suggest that the standard treatment of bleeding peptic ulcer based on starvation and sedation can no longer be universally accepted. Statistical studies go further and show that some patients with bleeding peptic ulcer will die from hemorrhage in spite of any form of medical treatment. Emery and Monroe,<sup>6</sup> reporting on 1,435 cases of peptic ulcer, found that 384 of their patients bled. Of these, twenty, or 5.2 per cent, died of hemorrhage. Allen and Benedict<sup>7</sup> studied 1,804 cases of duodenal ulcer and

found that 30 per cent of the patients bled. Of this number 138 had sudden severe hemorrhages, and for them the mortality was 14.5 per cent. Owen cited a mortality of 6 per cent in 137 cases of gross and massive hemorrhage from peptic ulcer. Twenty-six of his patients had massive hemorrhage from duodenal ulcer and six of these died, giving a mortality of 23 per cent, a figure which emphasizes the danger to life of massive hemorrhage from duodenal ulcer. Bulmer cited a mortality of 10 per cent, Hinton<sup>8</sup> of 11 per cent and Lahey<sup>9</sup> of 5 per cent. In contrast to these figures, Hurst and Ryle<sup>10</sup> reported a mortality from hemorrhage of 3 per cent in private practice and 4.8 per cent in hospital ward practice. Meulengracht reported a mortality of 1.3 per cent with his plan of feeding, his previous mortality with the old regimen of starvation and sedation having been 7.9 per cent. When one analyzes his reports, it would appear that his series is not strictly comparable with the cases of massive hemorrhage with possible surgical implications which are being considered here. His plan cannot yet be recommended.

Such varied mortality rates are puzzling until one remembers that, as Means<sup>11</sup> said, ". . . hemorrhage occurs under a variety of circumstances having different therapeutic significance. There are large exsanguinating hemorrhages; there are small ones carrying little risk. There are first hemorrhages and recurrent hemorrhages. There are hemorrhages in young persons and in old. All these factors have to be taken into consideration in planning treatment."

It seems fair to state that the mortality from massive hemorrhage complicating peptic ulcer, in this country at least, is 5 per cent or more with medical treatment. The mortality from massive hemorrhage complicating duodenal ulcer is definitely higher. The only hope for certain patients lies in early operation.

The attitude of the surgeon toward this complex and interesting problem should be characterized by a desire for close cooperation with the medical man in every case of hemorrhage. Patients should be hospitalized. All efforts should be made to arrive at a prompt and accurate diagnosis. In each case a decision as to whether the patient should be treated medically or whether surgical intervention alone can save him should be made within Finsterer's<sup>12</sup> time limit of from twenty-four to forty-eight hours from the onset of bleeding. The few patients who can be saved only by operation must be operated on early if they are to have every chance.

In making decisions of this nature, one can be guided somewhat by a few established facts. The incidence and the mortality of hemorrhage from ulcer is greater for men than for women. The incidence and the mortality of hemorrhage rise with age and with the presence of arteriosclerosis and hypertension. Hemorrhage from duodenal ulcer carries a higher mortality than hemorrhage from gastric ulcer. Hemorrhage from chronic ulcer is more likely to be fatal than hemorrhage from acute ulcer. Mortality rises rapidly with a second

or third massive hemorrhage closely following initial bleeding. According to Gordon-Taylor<sup>13</sup> the mortality from such a second hemorrhage is from 74 to 78 per cent. With regard to patients who survive, Lahey stated that 40 per cent of patients who have bled once will not be relieved of ulcer symptoms by medical treatment and that 80 per cent of patients who have bled two or more times will not be relieved of ulcer symptoms by medical treatment.

The mortality figures for surgical intervention vary greatly. However, when technic is fairly uniform, the principal factor which influences mortality is the time interval between the onset of hemorrhage and operation. Finsterer has demonstrated that the time element is all important. With thirty-five early resections for massive bleeding he had one death, or a mortality of 2.8 per cent; with forty-two late resections for massive hemorrhage he had thirteen deaths, or a mortality of 31 per cent. Resection is not always possible or necessary. With forty-two early operations of various types, all for severe bleeding, Finsterer had two deaths, or a mortality of 4.8 per cent. He maintained that this is the only fair figure to compare with mortality rates for medical treatment, for early operation means operation within twenty-four to forty-eight hours of the initial bleeding. What is more, this figure must be compared with the mortality for medical treatment in cases of massive hemorrhage and not with the rate for such treatment in general groups of consecutive cases.

The cases I shall report are consecutive cases of severe hemorrhage complicating peptic ulcer which were observed at the Lankenau Hospital during the past four years and at the Abington Memorial Hospital during the past twelve years. Only cases of gross hemorrhage, such as copious hematemesis or melena, frequently associated with syncope and always associated with weakness and a marked fall in the hemoglobin content and red count are included. Four surgeons and twelve medical men handled the patients. While the series is small, it throws some light on the incidence of ulcer complications in private patients and the better class of ward patients.

Table 1 shows the incidence of perforation and gross hemorrhage in all patients admitted during the time covered by this study.

Table 2 shows the distribution of the bleeding ulcers. As in most series, duodenal ulcer was the most frequent site of hemorrhage. Two of the anastomotic ulcers were jejunal, one occurring after a gastroenterostomy performed eleven years previously and the

other after a pylorotomy performed nineteen years previously. The third was gastric, occurring at the site of a sleeve resection done eight years previously.

Table 3 is a comparison of mortality rates with medical and with surgical treatment. The general mortality is 12.9 per cent, the mortality with medical treatment 7.5 per cent and the mortality with surgical treatment 22.7 per cent. Obviously the mortality with operation is higher than it should be. Twelve of the twenty-two operations were on patients who came to operation as medical failures, for whom the surgeon was first called in five or more days after the initial hemorrhage, often after one or more successive hemorrhages, and usually in the face of continued bleeding. Four of these twelve died, and the resulting mortality of 33 per cent represents the mortality for surgically treated medical failures. In the ten cases in which operation was the procedure of election, the only fatality resulted from bundle branch block, which developed on the eighth postoperative day during an otherwise smooth convalescence.

Table 4 is an analysis of the fatalities. The eight patients who died were all men. All but one were over 40. Five had duodenal and three had gastric ulcer. Without more detailed analysis, it may be noted that two fatalities resulted from radical operation for ulcer, two after indirect attack for ulcer and only one when the attack was made directly on the bleeding in the simplest operative fashion. In the last-mentioned case death resulted from bundle branch block after eight days of apparently uncomplicated postoperative recovery.

Table 5 shows the results of a follow-up study of the cases in which treatment was medical. Salient points are the few patients who completely recovered, the number of patients who had symptoms of ulcer and three cases of recurrent bleeding. The patients who

bled were men aged 57, 62 and 64, all with duodenal ulcer, and the last of these died of recurrent hematemesis thirteen months after discharge.

Table 6 is a follow-up study of the cases in which treatment was surgical. Points of interest are the high percentage of patients who recovered from all symptoms of ulcer and the two cases of recurrent bleeding. Of the eleven recoveries, six were after pyloroplasty combined with cauterization or suture of the ulcer,

13. Gordon-Taylor, Gordon: The Problem of the Bleeding Peptic Ulcer, Brit. J. Surg. 25: 403 (Oct.) 1937.

three were after posterior gastro-enterostomy and two were after gastric resection. At operation on one of the patients who bled after discharge from the hospital, a large ulcer was found near the common duct complicated by diffuse cholecystitis and chronic catarrhal appendicitis. The gallbladder and appendix were removed in the hope that the ulcer would then subside with medical treatment. Two months after discharge the patient died of hematemesis. This was an early

fusion the beneficial effect of blood is less and said that, if a second transfusion is necessary within forty-eight or seventy-two hours, one should transfuse and operate.

OPERATION

I believe that there are three groups of patients for whom operation is indicated. The first is that group with sudden massive hemorrhage who, according to the criteria just reviewed, are very likely to die with expectant or medical treatment. The second is the group who have severe recurrent bleeding with medical treatment. The third is the group who have recovered from an episode of hemorrhage but who continue to have symptoms of indigestion and high acidity or continued lesser bleeding in spite of medical treatment. Let me emphasize that, with each of these groups, after operation has been performed management along medical lines must continue indefinitely.

If early operation for bleeding is to be done, it should be performed only in cases of definite ulcer. Massive hemorrhage in a man over 50 who is known to have an ulcer and who does not rally soon after the initial hemorrhage is the most obvious indication. With the acute bleeding which occasionally is the first sign of ulcer but may be due to other lesions, the experience and judgment of the medical man and the surgeon conjointly must answer the question. When operation is undertaken, it should be done early, within twenty-four to forty-eight hours after the onset of bleeding, and it should be done with the sole intention of controlling the bleeding directly. By direct attack on the source of bleeding is meant direct localization and exposure of the ulcer, whether gastric or duodenal. At the time of operation one should give massive blood transfusion. In the more fortunate cases immediate resection, which includes the ulcer, may be done without greatly increasing the risk of operation. Surgical judgment is in the highest degree necessary. The important point is to regard the condition as an emergency requiring safe and immediate control of hemorrhage as a complication of ulcer rather than as an ulcer requiring radical operation for its cure. I have previ-

TABLE 6.—Follow-Up After Surgical Treatment (Sixteen of Seventeen Cases, or 92 Per Cent, Traced)

ously called attention to the value of anterior gastroduodenotomy in locating the source of hemorrhage at the operating table.<sup>16</sup> The following is a typical case:

CASE 1.—A large duodenal ulcer, almost 1 inch in diameter, was situated on the posterolateral duodenal wall. The patient had had two previous operations without the ulcer's being located. Over a period of eleven years he had bled severely on numerous occasions. The last two almost lethal hemorrhages had occurred within a period of three months. By

case, that of a man aged 39, and taught me to attack bleeding ulcers directly. The other patient with recurrent bleeding was a man aged 53 on whom pyloroplasty was performed for pyloric ulcer. Because of the recurrent bleeding, subtotal gastrectomy was advised.

From this series I have learned several lessons. Additional support is given to the fast accumulating evidence that an appreciable number of patients with bleeding ulcer will die of exsanguination with medical treatment alone. Fully realizing that most patients with initial hemorrhage recover with medical treatment, one must realize also that a certain percentage can be saved only by operation. Every patient with severe hematemesis or melena should therefore be hospitalized at once, and on arriving at the hospital the patient should be seen by a medical man and by a surgeon. The diagnosis of ulcer may have been made prior to hemorrhage or may be clear from the history. If not, the necessary and practicable steps should be taken to make it. Unless the bleeding continues unabated, barium sulfate may be given by mouth to aid in diagnosis. The danger in this procedure is not in the giving of the drug but in the transportation of the patient to the x-ray room and in the leaded glove of the examiner. Transportation should be done with care and deep palpation of the abdomen should be forbidden. The patient should be kept recumbent.

Within the first twenty-four hours every effort should be made to judge whether or not the individual is of the group of patients who are not likely to recover with medical treatment. According to Allen and Benedict the eventual survivors pick up rapidly after their first prostration. The prediction as to survival should be based on the severity and duration of bleeding, the patient's reaction to that bleeding, the patient's age and sex and the presence or absence of vascular disturbances. Allen<sup>14</sup> expressed the belief that the age of the patient has more bearing on the cessation of hemorrhage than any other factor, the mortality increasing greatly for patients over 50. The cases just cited indicate that patients between 40 and 50 should also be included in the dangerous group. Jones<sup>15</sup> suggested transfusions as an index to whether or not bleeding will continue. He pointed out that with each trans-

gastroduodenotomy a low posterior ulcer was found, an exposed vessel in the bed was sealed by electrocautery, the bed was cauterized, the craggy edges were nicked circumferentially and the operation completed as a wide pyloroplasty. The patient made an uncomplicated recovery and was free from bleeding or symptoms of ulcer four years later.

I repeat that, as a rule, I believe that the bleeding patient should not be subjected to too much surgical procedure. While the ulcer is bleeding is the time for the saving of life, not for the curing of the ulcer. The situation is somewhat similar to that in which operation is performed for intestinal obstruction due to colonic growths when obstruction is relieved at primary operation and the growth is later removed. The objective in the cases under discussion is hemostasis. Gastrotomy or duodenotomy will usually provide access to the ulcer. In the ulcer bed the actual bleeding point can frequently be found. The point may be sealed with the ball electrode, and an encircling stitch of chromic catgut may be placed through the tissues above and below. If the point is not discovered, similar procedures may still be adopted and it may be possible to mobilize overhanging edges and bring them together by suture. Small radiating incisions may be of advantage in the case of a large excavated ulcer. It is impossible to enumerate the precise procedures adapted to the varying individual cases, but it is important that uppermost in the surgeon's mind should be the immediate objective of controlling hemorrhage and not the ultimate desideratum of cure of the ulcer. A great advantage of anterior gastroduodenotomy for posterior ulcer is the opportunity afforded by it to terminate the operation as a gastroduodenostomy. While this procedure is not recommended as a definitely curative operation for ulcer, it would seem to be that in many instances. The mortality with such a procedure is extremely low. It may be done without exceeding the vitality of an exsanguinated patient, and it does not interfere with a subsequent radical operation should that be considered wise.

A case illustrative of these principles was observed at the Abington Memorial Hospital three weeks ago, too late to be included in the statistics just presented:

CASE 2.—A man aged 50, who had epigastric pain and vomiting characteristic of peptic ulcer for several days, in 1919 had a posterior gastro-enterostomy at another hospital for duodenal ulcer. The morning of admission he passed a large tarry stool, and he was admitted to the hospital in a state of shock. He rallied fairly well, but the next morning he vomited a large amount of bright red blood and again went into shock. The blood pressure fell to 80/30. The hemoglobin content was 55 per cent and the red count 3,200,000. Operation with massive transfusion was performed a few hours later. A gastrotomy gave ready access to a gastrojejunal ulcer with an open vessel in the bed. The ulcer was partially excised within the stomach and bleeding was stopped. The patient's convalescence has been perfectly smooth.

In cases in which bleeding has been controlled with medical treatment, operation must be considered because of the likelihood of another hemorrhage in the future. Here judgment is essential. Recurrent bleeding with medical treatment indicates progression of the ulcer, and operation should be performed. Subtotal gastrectomy with removal of the ulcer is usually the best curative procedure.

When bleeding has been controlled by medical measures but pain due to ulcer and high acidity persist in spite of treatment, resection should also be considered.

#### CONCLUSION

The treatment of gastric hemorrhage caused by a bleeding peptic ulcer is a complicated problem which calls for the pooled resources and close cooperation of the medical man and the surgeon.

A certain number of patients with bleeding ulcer will die with medical treatment. Every effort should be made to single these patients out and to give them the benefit of early operation.

At operation for bleeding ulcer, the primary consideration is hemostasis. After operation continued medical care should be the rule, and in selected cases more extensive surgical procedure should be considered.

### Council on Pharmacy and Chemistry

#### ERGONOVINE

##### Report of the Council on Pharmacy and Chemistry

THE COUNCIL HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT, WHICH HAS KINDLY BEEN PREPARED FOR THE COUNCIL BY DR. RALPH G. SMITH.

PAUL NICHOLAS LEECH, Secretary.

#### THE PRESENT STATUS OF ERGONOVINE

RALPH G. SMITH, M.D.

ANN ARBOR, MICH.

The recent discovery of a new and pharmacologically potent alkaloid of ergot has aroused considerable interest both in purely scientific and in clinical circles. Certain factors which have stimulated such interest are as follows: It is characterized by a number of physical, chemical and pharmacologic properties which differ decidedly from those of the previously known alkaloids of ergot, all of which show considerable similarity. Although hitherto unrecognized, it apparently plays an important role in the clinical oxytocic activity of those preparations of ergot which contain it and in the purified form is proving itself to be a valuable drug in the practice of obstetrics. Furthermore, the closely consecutive publications of its discovery from various laboratories naturally initiated discussion regarding priority.

As sufficient time has elapsed since the first announcements for general agreement on the properties of the alkaloid and for some indication of its therapeutic application, it is possible to describe its characteristics with a minimum of controversial discussion. However, before proceeding to that phase of the subject it might be of interest to review briefly the publications concerned with its early development.

Chassar Moir<sup>1</sup> in 1932, by means of the intra-uterine rubber bag method of Bourne and Burn,<sup>2</sup> recorded uterine contractions and tonus changes following the administration of various ergot preparations to puerperal patients. Several samples of B. P. liquid extracts

of ergot, prepared by aqueous extraction and containing only traces of the known ergot alkaloids, invariably produced, in 2 drachm (7.5 cc.) doses, a decided response which was more marked, especially with regard to tonus increases, than that produced by pure ergotoxine or ergotamine preparations administered by mouth or even by intramuscular injection. It having also been demonstrated that the activity of the liquid extracts could not be explained by their histamine or tyramine content, the action was ascribed to some still unknown factor.

Swanson and Hargreaves<sup>3</sup> in 1934 reported the comparative effect, as recorded by an intra-uterine rubber balloon, of various ergot preparations on the intact puerperal uteri of etherized dogs. On oral administration certain extracts and fluidextracts of ergot produced a definite response in from four to twenty minutes, while comparable doses, as determined by the cock's comb assay method, of ergotamine tartrate and ergotoxine ethanesulfonate brought about a similar effect only in from thirty to sixty minutes. Little difference in the various preparations was detected on intravenous administration. The conclusion reached was that "ergot contains a principle (not ergotamine or ergotoxine) that produces by mouth a rapid onset of action on the puerperal uterus of dogs."

Early in 1935 certain papers appeared from various sources which confirmed and extended these observations. Thompson<sup>4</sup> in January and March reported a study of various ergot preparations and fractions as recorded from the exposed uterus of the lightly anesthetized pregnant cat. (The two papers were previously presented at meetings of the American Pharmaceutical Association in August 1932 and May 1934 respectively.) According to the January report, hydro-alcoholic and aqueous extracts of ergot were prepared, containing the alkaloidal equivalent in 1 cc. of 0.5 mg. and 0.19 mg. respectively of ergotoxine ethanesulfonate as assayed by the Broom-Clark and cock's comb methods. These extracts produced a similar response, usually within ten minutes, in contrast to equivalent amounts of ergotoxine and ergotamine salts, which were more weakly effective and only in from thirty to sixty minutes after oral administration. Such results confirmed the work of Moir, suggesting the presence of some unknown potent principle which was considered as alkaloidal in nature. In the March paper were reported the method of separation of the new active substance in an amorphous form and certain of its properties, its smaller molecule and its greater solubility in water and numerous organic solvents in comparison with other ergot alkaloids being recognized. From the pharmacologic description, a very crude preparation was obviously concerned but a footnote reported its isolation in crystalline form. Thompson<sup>5</sup> later stated that the footnote was in the paper at the time of its submission for publication in May 1934 and in his doctorate dissertation, submitted before that time; also that the isolation in crystalline form was reported at the American Pharmaceutical Association meetings in May 1934 and that in the same month the name "ergostetrine" was assigned in a U. S. patent application. In a paper

delivered in April 1935 at a meeting of the American Society for Pharmacology and Experimental Therapeutics the alkaloid was referred to as ergostetrine, but in an abstract<sup>6</sup> of this paper published in June 1935 it is still called "X" alkaloid. The method of isolation appeared in September 1935.<sup>7</sup> Koff<sup>8</sup> reported in February 1935 a clinical investigation of ergot preparations by the intra-uterine balloon method, confirming Moir's conclusions regarding an unknown active substance in ergot. Also, on examination of Thompson's extracts he found the activity to lie wholly in the alkaloidal fraction, which still showed similar effects after removal of the ergotoxine group of alkaloids.

A publication by Davis, Adair, Rogers, Kharasch and Legault<sup>9</sup> appeared in February 1935 (previously presented at a meeting of the Central Association of Obstetricians and Gynecologists in November 1934) reporting the extraction of a water and alcohol soluble fraction from ergot which was considered to be non-alkaloidal on the basis of certain properties not characteristic of the known ergot alkaloids. This fraction in 3 mg. doses by mouth in more than 100 cases produced an increase in rhythm and tone in the quiescent puerperal uterus, beginning in fifteen minutes and persisting for from three to four hours after administration, as recorded by the intra-uterine balloon method. On the contrary, ergotamine, ergotoxine and sensibamine (now believed to be an equimolecular combination of ergotamine and ergotaminine<sup>10</sup>) in 3 mg. doses by mouth produced no effect over a period of one hour. The experiments here described were carried out with an impure substance, but in a footnote it was stated that the active principle had been isolated in crystalline form. In another footnote it was reported that a commercial firm had consented to make large quantities of the substance for clinical assay and had given it the name "ergotocin." The impression is given that "ergotocin" referred to the impure product, but Kharasch and Legault later state, in publications describing certain properties and clinical effects of the pure substance, that it referred to the crystalline product which had been obtained in December 1934<sup>11</sup> and which Eli Lilly & Co. had been preparing for two months and with which they had records on more than 200 patients.<sup>12</sup> A photomicrograph of the needle-shaped crystals of ergotocin, isolated by Kharasch, appeared on the cover of the March 1935 *Journal of Chemical Education*.<sup>13</sup> The empirical formula  $C_{21}H_{27}O_3N_3$  (which included a molecule of ethyl alcohol), assigned to the alkaloid by Kharasch and Legault, was published in June 1935.<sup>14</sup> The study of the chemistry of ergot was apparently begun by Kharasch and Legault early in 1932.<sup>15</sup>

5. Thompson, Marvin R.: The New Active Principle of Ergot, *Science* **81**: 636-639 (June 28) 1935.

The first detailed description of the method of preparation, physical properties and results of chemical analysis of the crystalline form of the new alkaloid, which they named "ergometrine" was published by Dudley and Moir<sup>16</sup> in March 1935. The analytic results were presented with reservation to allow slight modification after more drastic purification and no empirical formula was suggested at this time. Some modification of the analytic results and also of the physical properties was later found to be necessary. In the same paper, clinical results as recorded by the intra-uterine bag method and also by extra-abdominal recording apparatus were presented showing stronger and more prompt uterine activity on administration of the new alkaloid by mouth, intramuscularly or intravenously than that produced by the previously known ergot alkaloids. The former was also free from undesirable side actions. Some of the pharmacologic observations of Brown and Dale, such as the practical absence of epinephrine inhibiting effect, were included. The description of a method of preparation suitable for large scale operation was published later.<sup>17</sup>

In May 1935 Stoll and Burckhardt<sup>18</sup> reported the isolation in crystalline form of a new ergot alkaloid which they named "ergobasin" (referring to its comparatively strong basic reaction in aqueous solution), described the method of preparation and certain of its physical and chemical properties and presented photomicrographs of the crystals of the alkaloid and of certain of its salts. (It was later stated<sup>10</sup> that ergobasine had been prepared at the beginning of 1935.) On the basis of their analyses the empirical formula was announced as  $C_{19}H_{23}O_2N_3$ , which was confirmed by Jacobs and Craig,<sup>19</sup> who reported in July 1935 the isolation of the same alkaloid. The same formula was later accepted by Dudley,<sup>20</sup> by Davis, Adair and Pearl<sup>21</sup> and by Thompson.<sup>7</sup>

As a result of this contemporaneous work and the announcement in close succession of the isolation of the new alkaloid by four laboratories in Europe and America, considerable discussion naturally arose regarding priority.<sup>22</sup> At least a part of the confusion resulted from the uncertainty that all workers had isolated the same principle, since the initial announcements concerned preparations not absolutely pure and consequently differing slightly in physical constants and chemical properties. An exchange of samples among the four laboratories resulted in a mutual publication early in 1936 by Kharasch, King (in place of Dudley, then deceased), Stoll and Thompson<sup>23</sup> to the effect that ergometrine, ergotocin, ergobasin and ergostetrine were the same substance and that the four names were

synonymous. A detailed report of the comparison as carried out by Stoll and Burckhardt was later published.<sup>24</sup> Chen, Swanson, Kleiderer and Clowes<sup>25</sup> in a comparison involving action on the isolated rabbit uterus, the cock's comb and the *p*-dimethylamino benzaldehyde reactions and combustion analyses reached the same conclusion. Thompson<sup>26</sup> also reported identity on the basis of physical and pharmacologic characteristics.

On March 14, 1936, the Council on Pharmacy and Chemistry of the American Medical Association adopted the name "ergonovine" for the new ergot alkaloid,<sup>27</sup> since all of the names mentioned were either considered therapeutically suggestive (ergotocin, ergostetrine, ergometrine) or were proprietary (ergotocin, ergostetrine, ergobasin). Although the Council concedes to the discoverer the right to a proprietary name, in order to avoid confusion it is the policy to recognize only one such name for the same substance. In this case it was unable to establish undisputed priority so decided to allow no proprietary name. The action of the Council stimulated certain adverse criticism.<sup>28</sup> The names "ergometrine" and "ergobasin" are still being used in Europe.

Regarding priority, it is of interest that on June 13, 1932, about one week before the appearance of Moir's early paper,<sup>1</sup> Elmer H. Stuart of the Eli Lilly Company made U. S. patent application for an ergot-derived product and a process for obtaining it. This product was conceded to be a mixture but from its peculiar optical rotation ( $[\alpha]_D^{25} = -34^\circ$ ) in chloroform it was argued that it contained an alkaloid not hitherto described, in addition to ergotoxine and ergotamine, and having similar physiologic properties. In an amendment filed March 24, 1933, the high potency on the puerperal uterus in comparison to ergotamine and ergotoxine was stressed. From time to time patent claims were extended to cover properties as they were discovered, mostly by other investigators, which were confirmed for this mixture or for ergonovine separated from it. A patent covering all these properties was finally granted, Jan. 12, 1937. However, the Council on Pharmacy and Chemistry refused the claim, on the basis of this patent, of the Eli Lilly Company to the right of a proprietary name for the purified alkaloid, in that Stuart was not the first one to isolate it or to distinguish clearly its most important medical properties.

#### PHYSICAL AND CHEMICAL PROPERTIES

The alkaloidal base ergonovine is a colorless, tasteless, odorless, crystalline substance, appreciably soluble in water (1:200-300 at 20 C.<sup>18</sup>), showing in solution a weak but definitely alkaline reaction<sup>29</sup> and a bluish fluorescence.<sup>30</sup> In dilute aqueous solutions of organic and mineral acids it dissolves very readily.<sup>31</sup> It is freely

30. Dudley.<sup>22</sup> Stoll and Burckhardt.<sup>18</sup> Thompson.<sup>7</sup> Allport and Crews.<sup>34</sup> 31. Adair, Davis, Kharasch and Legault.<sup>15</sup> Kharasch and Legault.<sup>14</sup> Thompson.<sup>7</sup>

soluble in methyl and ethyl alcohol,<sup>32</sup> ethyl acetate, acetone, methyl ethyl ketone,<sup>33</sup> acetic ether,<sup>18</sup> less so in ether<sup>15</sup> and sparingly soluble in dichlorethylene,<sup>33</sup> benzene<sup>34</sup> and especially in chloroform.<sup>35</sup>

Ergonovine may be crystallized from a number of solvents, possibly most readily from benzene and chloroform, appearing in the form of long fine needles.<sup>36</sup> Characteristic crystallizations from other solvents have also been described.<sup>37</sup> A troublesome characteristic of ergonovine is a tendency for the crystals to retain some of the solvent in their formation and to release it only with comparatively drastic treatment.<sup>38</sup> This phenomenon apparently accounted for the erroneous empirical formula originally assigned by Kharasch and Legault, an equivalent of alcohol being retained in their preparation.<sup>39</sup>

A melting point with decomposition of 159-163 C. includes most of the values reported for the purified product,<sup>40</sup> although one as high as 164 C.<sup>54</sup> has been obtained. The optical activity, including specific rotation values [e.g.  $[\alpha]_D^{23} = +86^\circ$  ( $c = 0.199$ ) in water,<sup>24</sup>  $[\alpha]_D^{25} = -44^\circ$  ( $c = 0.08$ ) in chloroform<sup>41</sup>] which have been used extensively for identification purposes, has been described in numerous publications.<sup>42</sup>

In contrast to the other alkaloids which are precipitated in dilutions of from 1:200,000 to 1:2,000,000 by Mayer's reagent, ergonovine is not precipitated in dilutions above 1:5,000-1:10,000.<sup>43</sup>

A variety of crystalline salts have been prepared<sup>44</sup> and their characteristic crystal forms described.<sup>45</sup> The melting points<sup>46</sup> and optical activities have been reported for several of them, all preparations showing dextrorotation.<sup>47</sup> The water solubility of the salts is also high in comparison with other alkaloids of ergot, the maleate being soluble in water to the extent of 2 per cent at 38 C.<sup>18</sup>

Certain observations have been made regarding the stability of various preparations. Although aqueous solutions of the base are slowly oxidized on exposure to air, acquiring a brown color,<sup>49</sup> solutions in dilute polybasic aliphatic organic acids are stable at ordinary

temperatures and may be sterilized by boiling at 100 C. without appreciable loss in oxytocic activity and without imparting color to the solution.<sup>15</sup> The salts keep well in the dry state<sup>21</sup> or in solution in ampules,<sup>50</sup> although the heating of solutions of the salts in sealed tubes for any length of time results in decomposition and darkening.<sup>21</sup>

With regard to color tests characteristic of other ergot alkaloids and dependent on the indole nucleus, ergonovine gives positive glyoxylic acid, Keller and *p*-dimethylaminobenzaldehyde reactions.<sup>51</sup> The last reagent, used in the M. I. Smith colorimetric assay method, yields a more intense color with ergonovine than with the ergotoxine-ergotamine group when compared on a weight basis,<sup>52</sup> in keeping with the smaller molecular weight of ergonovine. Hampshire and Page<sup>53</sup> have obtained equivalent results with ergotoxine and ergonovine when compared on a molecular basis. The color produced by ergonovine in this reaction is spectroscopically identical with that produced by ergotoxine under the same conditions.<sup>54</sup> A positive color reaction has also been reported with the Folin-Denis phenol reagent.<sup>55</sup>

As already indicated, ergonovine,  $C_{19}H_{23}N_3O_2$ , has a definitely smaller molecule than ergotoxine,  $C_{35}H_{50}O_5N_5$ , and other alkaloids of ergot with the exception of ergomonamine.<sup>56</sup> On alkaline hydrolysis, it resembles the other alkaloids in yielding lysergic acid<sup>57</sup> but differs from them in the remaining part of the molecule. In the case of ergonovine this consists of a single and comparatively simple radicle *d*-2-amino propanol-1 ( $CH_3-CH.NH_2-CH_2.OH$ ).<sup>58</sup>

It is of interest that Smith and Timmis<sup>59</sup> have isolated from ergot and described the properties of an isomer of ergonovine (ergometrine) which they have named ergometrinine. This has been confirmed by Stoll,<sup>60</sup> ergobasinin. This alkaloid, in its physical properties, more closely resembles the older group of ergot alkaloids than does ergonovine. By suitable treatment these two alkaloids are interconvertible and constitute a pair of isomers corresponding to the pairs of previously known alkaloids ergotoxine ergotinine, ergotamine ergotaminine and the still more recently isolated ergosine ergosinine<sup>61</sup> and ergocristine ergocristinine.<sup>62</sup>

(According to Smith and Timmis<sup>63</sup> the ergoclavine of Kussner is a complex of ergosine and ergosinine.) Ergometrine, like one member in each of the foregoing pairs, is relatively inactive pharmacologically.<sup>64</sup>

A further step in the chemistry of ergonovine is reported by Stoll<sup>65</sup> in that he and Hofmann have synthesized ergobasini (ergometrine) from the pharmacologically inactive components lysergic acid and 2-aminopropanol-1 and in turn have converted the former into the pharmacologically active ergobasin (ergonovine).

#### PHARMACOLOGY

**Toxicity.**—Ergonovine appears to be from three to four times less toxic in mice, rats and rabbits than ergotamine<sup>66</sup> and ergotoxine.<sup>67</sup> On comparison with ergotamine it is ten times less toxic in the cock, intramuscularly, but of approximately equal toxicity in the cat subcutaneously.<sup>68</sup>

The manifestations produced by poisonous doses resemble those caused by the other alkaloids of ergot and are apparently due in no small part to the lysergic acid component of the molecule, as judged by the toxicity results with ergine, a simple amide of lysergic acid.<sup>69</sup> The most common signs of poisoning in the intact animal, which are essentially due to central action, are excitement, tremors, rapid respiration, weakness of the legs and general weakness, pyrexia, vomiting (in the cat on subcutaneous but not on intravenous injection<sup>67</sup>), convulsions and certain signs of sympathetic stimulation—mydriasis, exophthalmos, retraction of nictitating membrane, erection of the hair, vasoconstriction (ears pale and cold in the rabbit) and tachycardia. As a result of experiments on cats involving adrenalectomies and sympathectomies, Brown and Dale<sup>67</sup> conclude that such signs of sympathetic stimulation are a result to only a minor degree of peripheral action and are chiefly due to central stimulation. In rats the metabolic rate is increased by toxic doses of ergonovine.<sup>48</sup>

In fowl, toxic manifestations on intramuscular injection are also very similar to those produced by ergotoxine but probably less severe (incoordination, depression, dyspnea, staggering gait, drooping wings, salivation, diarrhea and comb changes<sup>67</sup>). The same typical picture, beginning in about five minutes, is produced by ergonovine when administered by mouth, whereas ergotoxine only after forty-five to sixty minutes usually produces a slight effect in comparison with that produced by injection.<sup>67</sup> Although ergonovine produces the characteristic cyanosis of the cock's comb<sup>70</sup> (and rat's tail<sup>71</sup>) there is general agreement

that it is much less liable to produce gangrene than is ergotamine and ergotoxine. Also the cyanosis appears somewhat sooner than with ergotoxine and persists for a much shorter time.<sup>67</sup>

**Circulatory Effects.**—Ergonovine injected intravenously into anesthetized rabbits and spinal cats causes a rise in blood pressure which, in the former animal, is more marked than that resulting from ergotoxine and ergotamine but less so in the latter.<sup>72</sup> In cats anesthetized with chlorbutanol the usual but not invariable effect is a feeble pressor response.<sup>73</sup> In vagotomized dogs under artificial respiration and chloralose anesthesia a strong pressor effect with renal vasoconstriction results.<sup>74</sup> Under evipal, a slight rise in blood pressure with a marked fall in kidney volume occurs.<sup>75</sup> Repeated doses result in a lessened pressor response or hypotension, as is characteristic with other ergot alkaloids.<sup>76</sup> In human subjects ergonovine produces practically no effects<sup>15</sup> or causes a slight increase in systolic and diastolic blood pressure with a slight slowing of the pulse, the effect being about half as great as that produced by ergotamine tartrate.<sup>77</sup>

In contrast, a fall in blood pressure is produced by ergonovine in anesthetized (ether, chloralose, evipal) cats<sup>78</sup> and etherized dogs.<sup>48</sup> Brown and Dale<sup>67</sup> believe that this depressor effect, which is accentuated by depressed respiration, is due to a depression of some vasomotor controlling center in the forebrain, the pressor effect being chiefly due to an action on spinal vasomotor centers rather than to peripheral effects. "The vasomotor effects of the alkaloid are the resultants of a complicated antagonism of actions at different levels."<sup>67</sup>

In contrast to the vasodilatation produced on perfusion of the hind limbs of the cat,<sup>67</sup> the leg vessels of the frog<sup>48</sup> and the ear vessels of the rabbit<sup>68</sup> are constricted by ergonovine.

The action on the heart itself appears to be unimportant in the production of the circulatory effects. Although decrease in the rate and amplitude of the frog heart on perfusion with ergonovine  $1:10^4$  has been observed,<sup>48</sup> negative results have been reported from experiments on the isolated cat<sup>66</sup> and rabbit<sup>67</sup> heart.

In the rabbit, ergonovine inhibits the effect of stimulation of the depressor nerve but is only about one-half as strong in this regard as ergotamine.<sup>74</sup>

**Uterine Action.**—The high sensitivity of the human uterus to ergonovine emphasized in earlier reports<sup>79</sup> is in agreement with the results of animal experimentation in which uterine stimulation is the only specific effect produced by small doses of the alkaloid.

Ergonovine in very high dilutions ( $1:2 \times 10^6$ ,  $1:3 \times 10^6$ ,  $1:5 \times 10^6$ ,<sup>1</sup>) stimulates the isolated rabbit uterus to prompt and prolonged rhythmic contrac-

tions<sup>60</sup> in contrast to the relative lack of sensitivity to ergotoxine.<sup>61</sup> Rothlin records the effect on the rabbit uterus in vitro<sup>68</sup> and in situ<sup>82</sup> as being twice as strong as that of ergotamine corresponding to their molecular weights and states that it is more easily washed out in vitro than ergotamine.<sup>82</sup> A much greater difference between the effective doses of these two alkaloids on the puerperal rabbit uterus in situ is indicated by other work.<sup>83</sup>

The isolated uterus of the virgin guinea pig is even more sensitive,<sup>81</sup> responding to dilutions of 1:10<sup>7</sup>,<sup>85</sup> 1:2 × 10<sup>7</sup>,<sup>48</sup> or even to 1:10<sup>9</sup>.<sup>67</sup> However, this preparation shows equal sensitivity to ergotoxine, although the response to the former drug is slightly more abrupt.<sup>67</sup> In the guinea pig as in other animals the most striking effects are on the uterus in situ, within a few days after parturition, the response to intravenous injection being more prompt than with ergotoxine and stimulation of rhythm being the outstanding effect, whereas increases in tone predominate with the latter drug.<sup>67</sup>

Ergonovine increases the tone and activity of the nonpregnant cat uterus, virgin or parous, but in a manner indistinguishable from ergotoxine and ergotamine, as is also true in the early stages of pregnancy. However, the puerperal uterus shows striking sensitivity, ergonovine 1:75 × 10<sup>6</sup> initiating contractions continuing for hours in otherwise quiescent isolated preparations.<sup>67</sup> The uterus in situ behaves similarly,<sup>67</sup> responding to doses of from 0.05 to 0.1 mg. intramuscularly, while ergotamine usually produced no activity in doses up to 2 mg.<sup>83</sup>

A high degree of sensitivity has also been reported for the puerperal dog uterus in situ.<sup>86</sup>

Abortion has been produced in animals by ergonovine, but the results are too variable and few in number to justify a definite statement regarding the necessary dosage and probability of occurrence.<sup>87</sup>

Apparently the outstanding features of the action of ergonovine on animal uteri are manifested in the puerperal period when its prompt action and its effectiveness in small doses or high dilutions distinguish it from ergotoxine and ergotamine. The uterus in situ responds essentially by increased rhythmic contractions,<sup>88</sup> continuing for hours,<sup>80</sup> although an increase in tone is a prominent effect in the initial stages of the action.<sup>90</sup>

**Sympathomimetic Action.**—Ergonovine produces mydriasis on local application,<sup>48</sup> and mydriasis and exophthalmos in the general action of toxic doses in rabbits and cats in contrast to ergotoxine<sup>67</sup> and ergot-

amine,<sup>91</sup> the usual effect of which in the cat is myosis. A relaxation of the isolated intestine of the rabbit is produced, which may be prevented by ergotoxine<sup>48</sup> or ergotamine.<sup>10</sup> In contrast, the guinea pig's jejunum responds by a tonic contracture, which may also be annulled by ergotoxine,<sup>67</sup> and Thompson<sup>75</sup> reports relaxation followed by contraction of the isolated intestine of the guinea pig. Even the response of the isolated uterus of the rabbit is diminished by ergotoxine,<sup>92</sup> just as the latter drug abolishes the effect of epinephrine on this tissue. The blood sugar of the rabbit and dog is increased very little by ergonovine, but it increases the action of epinephrine in this regard.<sup>93</sup> Such observations indicate a peripheral sympathomimetic action, although, as already mentioned,<sup>67</sup> the manifestations of sympathetic stimulation in the intact animal may be due principally to a central effect.

**Epinephrine Inhibiting Action.**—Neither the general pressor response of epinephrine<sup>94</sup> nor its vasoconstricting effect in the kidney and intestine in situ,<sup>66</sup> in the Laewen-Trendelenburg frog perfusion<sup>48</sup> and in the perfusion of the hind limbs of the cat,<sup>67</sup> is prevented by ergonovine as it is by ergotoxine and ergotamine. The same failure of ergonovine to inhibit the action of epinephrine has been demonstrated on the rabbit uterus<sup>95</sup> and the seminal vesicle of the guinea pig.<sup>96</sup> However, it may not be entirely devoid of this action, as it has been observed to some degree on the circulatory system<sup>97</sup> and uterus<sup>98</sup> after very large and repeated doses. Even when such action does appear on in vitro preparations it may be removed by a change in solution, which is not possible with ergotoxine.<sup>67</sup>

**Additional Actions.**—Large doses of ergonovine produce an increase in rate but a decrease in the volume of respiration in cats and rabbits,<sup>66</sup> the respiratory center of the cat being more strongly affected than with ergotamine.<sup>91</sup> Toxic amounts lower the temperature of the mouse<sup>98</sup> and increase that of the cat and rabbit,<sup>99</sup> the latter effect being greater than that with ergotamine.<sup>91</sup> Ergonovine, in doses not producing side actions, produces diuresis in dogs in contrast to the antidiuretic action of ergotoxine and ergotamine.<sup>100</sup> This action is not observed clinically.<sup>15</sup> In vitro it inhibits the splitting of acetylcholine by choline esterase.<sup>101</sup>

**Occurrence and Assay.**—It was recognized early in the investigation of ergonovine that it did not occur in constant amounts in all specimens of ergot, and in certain samples (e.g. Russian ergot in contrast to Spanish and Portuguese ergots) it was entirely lacking.<sup>102</sup> Even ergots obtained from one locality may vary in this regard.<sup>103</sup> The results of various workers indicate a content of from 0.05 to 0.2 mg. per gram

of ergot in samples which contain it.<sup>104</sup> Of course, a part of this variation may be due to the efficiency of isolation and to the purity of the final product. In any case it is present in much smaller concentrations than the ergotoxine-ergotamine group, which may reach 2 mg. per gram<sup>105</sup> and according to U. S. P. requirements must be 0.5 mg. per gram.

Owing to such variations in occurrence and to the marked activity of ergonovine on the uterus in comparison with that of other ergot alkaloids, the problem of assay is of great importance and has been considered in numerous publications.<sup>106</sup> The assay of pure preparations of ergonovine uncontaminated by other alkaloids of ergot is a comparatively simple problem, a variety of tests being applicable.<sup>107</sup> However, in crude preparations containing such other alkaloids as ergotoxine and ergotamine it becomes more difficult, since the latter produce comparable results in the colorimetric and cock's comb methods. Consequently such assays would be a measure neither of the content of any particular alkaloid nor of the clinical potency of the preparation. Although ergonovine has a much stronger effect than the other alkaloids on the isolated rabbit uterus, even by this method the presence of the latter substances and also of amines in galenic preparations would be complicating factors. This is especially true, if, as already stated, the response of the isolated rabbit uterus to ergonovine is diminished by ergotoxine.<sup>108</sup> It would appear that a separation of ergonovine from the other group of alkaloids would be necessary before assay, unless such assays were made clinically on the postpartum human uterus. Assays by the colorimetric method<sup>109</sup> and on the puerperal cat or rabbit uterus *in situ*<sup>83</sup> involving a previous separation have already been proposed. Naturally the usefulness of such methods must be learned by further experience with them. Of course, a simpler solution of the problem from the therapeutic point of view would be the use of pure alkaloids rather than of galenic preparations. Such a practice would also be desirable with regard to the production of the specific effects of the individual alkaloids.<sup>10</sup>

#### CLINICAL INVESTIGATIONS

*Effective Dosages and Character of Action.*—It was early observed that the postpartum uterus is extremely sensitive to ergonovine. Effective dosages originally cited by Dudley and Moir<sup>16</sup> were from 0.5 to 1 mg. orally, from 0.25 to 0.5 mg. intramuscularly and from 0.05 to 0.1 mg. intravenously. Positive effects have been produced with less than 0.05 mg. intravenously, although 0.2 mg. has been described as an optimal intravenous dose and 0.4 mg. is considered suitable for administration by mouth, sublingually or intramuscularly.<sup>15</sup> Typical responses may be obtained, however, from 0.2 mg. by mouth.<sup>21</sup> Doses of approximately this range have proved effective in other investigations<sup>110</sup>

and have been safely increased to 1.5 mg. by mouth and 0.75 mg. intramuscularly.<sup>111</sup>

The rapidity of response has proved to be a distinctive feature in contrast to the prolonged latent period characteristic of the other alkaloids. The time elapsing between administration and effect is approximately from six to eight minutes, from three to four minutes and from one to two minutes or less after administration by mouth, intramuscularly and intravenously respectively. On the contrary, ergotoxine and ergotamine, in doses by mouth as high as 3 mg. or more, which produce unpleasant side effects, may cause no action on the uterus or the action may appear only after a latent period of from one half to three quarters of an hour or longer.<sup>112</sup> Even on injection, twenty minutes may elapse before the onset of action.<sup>111</sup>

The character of the response has also been described in detail in these studies. On the quiescent postpartum uterus an intravenous injection results in an abrupt increase in tone developing over the course of about fifteen seconds. This is followed by slight and increasing contractions with some fall toward normal in tone, the record henceforth resembling that following administration by other routes.<sup>15</sup> In the latter cases the development in tone is less rapid, with slight contractions which gradually become less frequent. The early phase of the action, lasting for from forty-five to ninety minutes, has been described as a tonicoclonic stage in which a tonic contraction is the predominant feature.<sup>113</sup> The early spasm is considered to be due to contractions following each other in such close succession that the uterus does not have time to relax.<sup>50</sup> With a gradual decrease in tone accompanied by a greater prominence of rhythmic contractions this phase gradually changes into one lasting up to three hours or longer characterized by successive rhythmic contractions with complete relaxation intervening, the contractions becoming less frequent and weaker as the effect subsides. The tonic element of the action is apparently less marked than that resulting from ergotoxine and ergotamine,<sup>111</sup> the tonus increase being proportionately small in relation to the rhythmic contractions produced.<sup>114</sup>

*Duration of Action.*—The early assumption<sup>115</sup> that the action of ergonovine on the uterus is abrupt and transient in comparison with a more persistent effect produced by ergotoxine and ergotamine might well have been inferred, owing to its high water solubility and consequent easier removal from its site of action, as indeed has been observed in *in vitro* experiments.<sup>82</sup> However, in both animal<sup>80</sup> and clinical<sup>116</sup> investigations it has been demonstrated that the action persists for from three to four hours or longer. Rothlin,<sup>117</sup> Stoll,<sup>60</sup> Heyrowsky<sup>118</sup> and Wirth<sup>119</sup> consider this duration of action to be overestimated on account of the possible contamination with ergotoxine and ergotamine

of the ergonovine preparations used and on account of the previous administration of ergotoxine or ergotamine in certain clinical experiments which might account for the prolonged action observed. However, it is doubtful whether such criticisms could apply in many instances. Although the action may persist as stated, the duration of the spasm may be only half that of the ergotamine-ergotoxine group and the total duration of the effect probably less than that of these alkaloids.<sup>120</sup>

**Side Actions.**—A favorable aspect in the clinical use of ergonovine is the rarity of undesirable side actions, which frequently occur with the other alkaloids,<sup>121</sup> and posterior pituitary extract.<sup>122</sup> In one series of more than 200 cases in which 0.25 or 0.5 mg. of ergonovine was administered orally, no side actions were observed.<sup>114</sup> However, in a few cases nausea and vomiting has been encountered,<sup>15</sup> and Moir<sup>123</sup> reports three instances of unusual reactions.

#### THERAPEUTIC USES

Before the onset of labor the uterus is apparently somewhat insensitive to the action of ergonovine,<sup>50</sup> although some effect has been reported.<sup>121</sup> It gave inconclusive results when it was tried in a few cases for the induction of labor<sup>15</sup> and for the interruption of a four to five months pregnancy.<sup>114</sup> Also in cesarean section the uterus does not respond to ergonovine before removal of the fetus unless labor has already commenced.<sup>50</sup>

Its administration in labor before the birth of the child is considered unsafe<sup>125</sup> although it has been used in a few selected cases of uterine inertia in the second stage of labor with successful results.<sup>114</sup>

Ergonovine probably finds its most extensive application in the treatment of postpartum hemorrhage, having been successfully used in several series of cases.<sup>126</sup> It is probably more reliable for this purpose than posterior pituitary extract.<sup>127</sup>

If necessary it may be safely used in the third stage of labor in doses of approximately 0.25 mg. by injection or by mouth, as indicated by several investigations involving this procedure.<sup>128</sup> The usual but not invariable result has been rapid placental separation and expulsion with minimal bleeding. Moir<sup>111</sup> favors its use in cases of third stage hemorrhage or on failure of simple methods to produce placental expulsion but not as a routine procedure.

The final answer regarding the use of ergonovine in the puerperium has not been reached, although there have been several controlled studies in this regard. Davis, Adair and Pearl<sup>21</sup> and Wirth<sup>119</sup> report favorably concerning its action in reducing foul lochia, lochial obstruction, subinvolution and morbidity. Der Brucke<sup>129</sup> and Tuck<sup>130</sup> (ergoklonin) also consider it

to be of benefit. On the contrary, Moir<sup>121</sup> reached the tentative conclusion that its routine use in the puerperium offered no advantages and considered it contraindicated in the presence of uterine sepsis.

Uniformly satisfactory results are reported for its use in cesarean section with respect to prompt separation of the placenta and the control of hemorrhage. It has been injected as the baby was delivered,<sup>15</sup> before incision of the uterus,<sup>50</sup> and directly into the uterine wall after extraction of the baby.<sup>119</sup>

It would appear that ergonovine is worthy of further trial in the treatment of incomplete abortion.<sup>121</sup> Although not all reports are favorable regarding the expulsion of retained secundines, it is undoubtedly of value in the control of bleeding.

After diagnosis it may be of value as a palliative and temporary measure in certain cases of menorrhagia and metrorrhagia until the underlying pathologic condition can be corrected.<sup>133</sup>

Positive results have been reported for the relief of migraine headache by ergonovine, although it was effective in a much lower percentage of cases than was ergotamine.<sup>77</sup>

**Importance of Ergonovine.**—The isolation and clinical trial of ergonovine has prompted the expression of various opinions regarding its importance in the realm of ergot therapy. Dale<sup>131</sup> and Dudley and Moir<sup>18</sup> consider it of greater therapeutic importance than all the hitherto known alkaloids of ergot and believe that it forms the basis for ergot therapy at least as far as the uterine action is concerned. It is suggested that the presence of the other alkaloids may actually have a deleterious effect. Moir<sup>50</sup> expresses the belief that it should be used wherever there are indications for ergot therapy and that it completely supplants the older preparations.

Adair<sup>15</sup> hails it with similar enthusiasm, considering it the active principle which is responsible for most if not all of the desirable oxytocic effect of ergot. Runge<sup>114</sup> and Küssner<sup>135</sup> also seem to agree that it is of prime importance in ergot therapy. Stoll<sup>136</sup> considers such opinions too sanguine: Owing to the small amounts of ergonovine in many ergots, the traditional action of the crude drug may not be wholly explained by its presence. Also in the light of its presumably short duration of action it plays only a limited role in ergot therapy and should be supplemented by a drug with a more persistent action when this is desired. Furthermore, it has been pointed out by Rothlin and Löffler<sup>10</sup> that it at least cannot replace ergotoxine and ergotamine in the treatment of those conditions in which the inhibiting effect on the sympathetic nervous system is indicated. The wide therapeutic use which already exists will undoubtedly settle such differences of opinion in the near future.<sup>137</sup>

## SUMMARY

Ergonovine, an alkaloid of ergot, was isolated independently and by contemporaneous work in four laboratories.

It crystallizes readily and forms a variety of crystalline salts; characteristic physical properties have been described for both the base and the salts.

In contrast to other alkaloids of ergot, ergonovine is appreciably soluble in water and comparatively insoluble in chloroform; its salts are markedly soluble in water.

It is less readily precipitated by Mayer's reagent than other ergot alkaloids but gives the characteristic color reactions of this group. The color developed with *p*-dimethylaminobenzaldehyde is quantitatively greater than with the other alkaloids, in keeping with the smaller molecule of ergonovine.

Ergonovine,  $C_{19}H_{23}O_2N_3$ , consists of a combination of lysergic acid, common to all ergot alkaloids, and *d* 2-amino propanol-1.

In the intact animal and in human subjects the only appreciable effect of moderate doses is on the uterus, which is especially sensitive in the puerperal state. It is effective in smaller doses and concentrations than are other ergot alkaloids, such doses being remarkably free from unpleasant side actions. It is further characterized by its prompt action even when administered by mouth. It increases both the tone and the rate and amplitude of rhythmic contractions of the uterus, the latter effect probably being proportionately greater than the tonus changes. The duration of the effect, although probably less than that of ergotoxine and ergotamine, is at least comparable with that of the latter alkaloids.

It is less toxic than ergotoxine and ergotamine but in poisonous doses produces effects similar to those of the latter alkaloids. Although ergonovine produces the characteristic cock's comb reaction, it shows definitely less tendency to produce gangrene than ergotoxine and ergotamine.

The circulatory effects, which are referable to actions on the central nervous system and peripheral vascular mechanism rather than to cardiac effects, vary with the animal and with experimental conditions.

Ergonovine shows a definite sympathomimetic effect and little or no inhibition of epinephrine action.

It may be assayed by a variety of procedures when in the pure form but at present cannot be quantitatively determined in the presence of other alkaloids of ergot. Suggested methods involve a separation of ergonovine from the ergotoxine-ergotamine group before assay.

Its greatest clinical value appears to be in the treatment of postpartum hemorrhage, being safely administered at the beginning of the third stage if necessary. Likewise it has been of value in the control of hemorrhage following cesarean section. Many investigators favor its use in the puerperal period for the promotion of involution and the prevention and control of sepsis, but this use is not universally accepted. Variant results have also been obtained in the treatment of incomplete and inevitable abortion. It may be used as a palliative measure in certain cases of menorrhagia and metrorrhagia.

Many authorities believe that ergonovine forms the basis for all ergot therapy involving uterine action and that it is responsible for the traditional effect of ergot, while others are less enthusiastic concerning its value.

## Council on Foods

## ACCEPTED FOODS

THE FOLLOWING PRODUCTS HAVE BEEN ACCEPTED BY THE COUNCIL ON FOODS OF THE AMERICAN MEDICAL ASSOCIATION AND WILL BE LISTED IN THE BOOK OF ACCEPTED FOODS TO BE PUBLISHED.

FRANKLIN C. BING, Secretary.

MRS. PALEY'S BABY FOOD—  
STRAINED APPLES

*Manufacturer.*—Paley-Sachs Food Company, Houston, Texas.

*Description.*—Canned cooked sieved apples, containing a small amount of added dextrose.

*Manufacture.*—Colorado Jonathan apples are thoroughly washed, trimmed, inspected, cooked in air-tight steam pressure cookers for five minutes with added dextrose, sieved, filled into glass jars and heat processed.

*Analysis* (submitted by manufacturer).—Moisture 77.4%, total solids 22.6%, ash 0.3%, fat (ether extract) 0.1%, protein ( $N \times 6.25$ ) 0.2%, reducing sugars as dextrose 15.7%, sucrose 1.7%, crude fiber 0.8%, total carbohydrates other than crude fiber (by difference) 21.2%, calcium (Ca) 0.006%, phosphorus (P) 0.02%, iron (Fe) 0.0008%.

*Calories.*—0.9 per gram; 25.6 per ounce.

## CLAPP'S PUREE OF GREEN BEANS

*Manufacturer.*—Harold H. Clapp, Incorporated, Rochester, N. Y.

*Description.*—Canned sieved green beans, seasoned with salt.

*Manufacture.*—Fresh green beans, grown under contract with the manufacturer, are cleaned, sorted, washed, again sorted, and precooked under pressure in an atmosphere of steam. Salt is added and the partially cooked beans are sieved in an atmosphere of steam, vacuum treated to attain the desired consistency, automatically filled into cans, and heat processed.

*Analysis* (submitted by manufacturer).—Moisture 91.5%, total solids 8.5%, ash 0.8%, fat (ether extract) 0.2%, protein ( $N \times 6.25$ ) 1.6%, crude fiber 0.9%, carbohydrates other than crude fiber (by difference) 5.0%.

*Calories.*—0.3 per gram; 8 per ounce.

## CELLU BRAND ORANGE JUICE

*Distributor.*—Chicago Dietetic Supply House, Inc., Chicago.

*Description.*—Canned California Valencia orange juice.

*Manufacture.*—Manufactured in essentially the same manner as Treesweet Pure California Orange Juice (THE JOURNAL, June 15, 1935, p. 2187).

*Analysis* (submitted by manufacturer).—Moisture 85.9%, total solids 14.1%, ash 0.4%, fat (ether extract) 0.1%, protein ( $N \times 6.25$ ) 1.1%, reducing sugar as invert 5.6%, sucrose (by copper reduction) 4.8%, crude fiber 0.02%, carbohydrates other than crude fiber (by difference) 11.5%, titratable acidity as citric acid 1.0.

*Calories.*—0.51 per gram; 14 per ounce.

MRS. PALEY'S BABY FOOD—STRAINED  
EVAPORATED PEARS

*Manufacturer.*—Paley-Sachs Food Company, Houston, Texas.

*Description.*—Cooked, sieved, sulfured dried pears, packed with added dextrose.

*Manufacture.*—Dried sulfured pears are washed, soaked, pressure cooked with added dextrose, strained, filled into glass jars, vacuum sealed and heat processed. A small amount of lemon juice is added for flavor.

*Analysis* (submitted by manufacturer).—Moisture 72.4%, total solids 27.6%, ash 0.5%, fat (ether extract) 0.1%, protein ( $N \times 6.25$ ) 0.6%, crude fiber, 1.4%, reducing sugars as dextrose 13.2%, sucrose 2.2%, total carbohydrate other than crude fiber (by difference) 25.0%, iron (Fe) 0.0011%, phosphorus (P) 0.025%, calcium (Ca) 0.021%, sulfur dioxide (SO<sub>2</sub>) 0.033%.

*Calories.*—1 per gram; 28.4 per ounce.

SATURDAY, DECEMBER 10, 1938

## GAS GANGRENE

All recent reports on gas gangrene in man agree essentially on the increase of this condition in civil life. Following injuries sustained in the World War gas gangrene was common. Today the condition is becoming more important because of the more frequent occurrence of crushing wounds and lacerations following traffic and industrial accidents. While its frequency is difficult to determine accurately, the increasing reports in the literature seem to offer sufficient evidence of its widespread nature.

A recent review<sup>1</sup> of the morbidity and mortality due to gas gangrene in New York State exclusive of New York City, while admittedly incomplete, reports 208 hospitalized cases between 1932 and 1936. These cases are placed in four groups: those presenting records positive for gas gangrene clinically and bacteriologically, those presenting records incomplete but with sufficient evidence to be included as gas gangrene, those presenting records that made the diagnosis questionable and those in which the data were too incomplete for an accurate diagnosis. With the omission of the last two groups 135 cases were recorded, ninety-one of them resulting from trauma, thirteen from clean amputations, seven from pregnancy, five from gunshot wounds and nineteen from miscellaneous causes. When compared with the incidence of tetanus, infection by this group of spore-bearing bacteria is probably as frequent. According to White,<sup>2</sup> gas infection usually occurs in four types of wounds: crushing injuries in which the skin is torn, puncture wounds with a great deal of hemorrhage, particularly if a foreign body has been implanted, extensive lacerations of tissues with gross soiling with dirt, and badly soiled compound fractures. Ramsay<sup>3</sup> states that gunshot wounds and compound

fractures offer the most favorable environmental conditions for the development of *Clostridium welchii* or other spore-bearing anaerobes, since damaged muscle tissue is the perfect medium for the growth and development of these organisms. Less commonly, gas gangrene has been reported following abortion<sup>4</sup> and as a result of hypodermic injection.<sup>5</sup> Organisms of this group, including *Clostridium welchii*, *Vibrio septique* and *Clostridium oedematiens*, are so widely distributed in nature that little can be done to eradicate the source of infection.

The best treatment for gas gangrene is prophylactic. Penfold and Tollhurst<sup>6</sup> have reported promising attempts at the immunization of animals and man with alum-precipitated formol toxoid made from *Clostridium welchii* toxin. After preliminary work on experimental animals volunteers were treated with the toxoid and the level of antitoxin was measured at various intervals thereafter. The evidence presented, they believe, suggests that this toxoid is suitable material for immunizing man against gas gangrene due to *Clostridium welchii*, although the level of antitoxin necessary for protection has not as yet been determined. Auspicious as this work may be, it is not likely that the frequency of gas gangrene in peace time is such that mass immunization is likely to be a practical preventive measure in the near future.

The prophylactic treatment of patients who have extensive lacerations or other injuries which are recognized as predisposing to gas gangrene has been carefully outlined in a number of the recent discussions. Lower and Tormey<sup>7</sup> state that in carrying out a débridement properly it is important that adequate exposure of the depths of the wound be obtained. The wounds in which dead spaces or pockets are apt to occur are best cared for by placing Dakin tubes in their depths through which irrigation may be carried out every two hours. They also recommend the use of a prophylactic dose of polyvalent gas bacillus antitoxin (and tetanus antitoxin) to every patient with extensive or suspicious wounds. Although Malone<sup>8</sup> believes that a larger dose of *Clostridium welchii* antitoxin is to be preferred to the polyvalent antitoxin usually supplied, the majority seem to agree that the polyvalent antitoxin in suitable quantities is satisfactory.

In spite of suitable precautionary measures there are some instances in which gas gangrene develops, and treatment therefore becomes of paramount importance. Surgical exploration with the introduction of air and probably diluted solution of sodium hypochlorite should

in this event be employed at once. The use of antitoxin in large quantities intramuscularly or intravenously or in some cases around the infected area is also a procedure to be employed promptly.

The use of x-rays has been reported favorably,<sup>9</sup> and in the past few months several reports on the favorable effect of sulfanilamide or its derivatives in gas gangrene have appeared.<sup>10</sup> The effectiveness of prophylactic measures and improvement and addition of therapeutic techniques for dealing with this disease should do much to minimize its dangers.

#### ANTIGENIC STRUCTURE OF SPERMATOZOA

The recent demonstration of a head-specific and a tail-specific antigenic fraction in mammalian spermatozoa, with a third or species-specific antigen common to the heads and the tails, is of basic biologic and immunochemical interest. Separation of spermatozoa into head and tail fractions was attempted forty years ago by Miescher.<sup>1</sup> He found that if fish spermatozoa are suspended in distilled water the relatively heavy heads can be broken off by carefully graduated centrifugation. Mammalian spermatozoa, however, cannot be broken up by this technic. Henle and his colleagues<sup>2</sup> of the Johnson Foundation for Medical Physics, University of Pennsylvania, have recently attempted such fragmentation by the modern technic of supersonic vibration. They found that bull, dog or rabbit spermatozoa were fairly completely broken up into head and tail fractions by exposure for seven minutes to vibrations of 9,000 cycles per second. Guinea pig spermatozoa required fifteen minutes and human spermatozoa twenty minutes for similar fragmentation. Final separation of the head and tail fragments was effected by fractional centrifugation. By repeated washings, head and tail suspensions can often be obtained 99 per cent pure. This degree of purity was confirmed by the use of a blood counting chamber and by a study of stained smears. Cleavage occurred uniformly at the junction of the midpiece and head except with human spermatozoa. With human cells a small part of the midpiece often remained with the head. No difference was noted in the microscopic appearance of the heads after separation, except with guinea pig spermatozoa, which often lost their acrosoma.

The Pennsylvania investigators immunized rabbits against the head and tail fractions and against the intact spermatozoa of four different animal species. Tests of

antigenic specificity were made by the complement fixation technic with confirmatory tests by slide agglutination. As shown by other investigators, cross reactions were obtained with the intact spermatozoa of different animal species. Cross reactions were obtained also with the head and tail fractions of the same animal species. By proper absorption of the antisera, however, highly specific fractional antibodies were demonstrated. Thermolabile tail-specific and head-specific antigen fractions were thus recognized, as well as a coctostable heterophile or nonspecific fraction common to heads and tails. A fourth, nuclear-specific, fraction is suspected, not demonstrable in intact spermatozoa but readily demonstrable in the broken-off heads. Antibodies against this hypothetical nuclear-specific antigen are not formed on injection of intact spermatozoa but are formed when vibrated heads are injected. Whether or not the suspected nuclear antigen is a protein or a lipid has not yet been determined.

The results obtained by the complement deviation technic were confirmed by a study of slide agglutination. Two types of agglutination were noted. The first was a head-specific agglutination or clumping of the heads, with the formation of a rosette of moving tails. The second was a tail-specific agglutination with adhesion or clumping of the tips of the tails. The latter resulted in a rosette of moving heads. Combined head and tail agglutination was obtained with native antisera against intact spermatozoa, with a resulting netlike entanglement of whole cells.

Immunologists of the future may conceivably regard Henle's work as of basic historical interest, the first successful attempt at a serologic dissection of mammalian tissue cells. There seems no reason why some modification of his technic cannot be applied to other mammalian tissues.

#### NEW JERSEY MOSQUITOES AS POTENTIAL CARRIERS OF YELLOW FEVER

The demonstration by Bennett and his colleagues<sup>1</sup> of the Harvard Medical School that the common New Jersey mosquito is capable of transmitting yellow fever to monkeys seems to throw doubt on the conventional assumptions for other insect-borne diseases. Following experimental proof by Reed, Carroll and their co-workers in 1900-1901 that the subtropical mosquito variously known as *Aedes aegypti*, *Stegomyia fasciata* or *Aedes argentens* is capable of transmitting yellow fever to man, it was quite generally assumed by hygienists that this is the only species of mosquito capable of transmitting this infection. It was alleged in support of this assumption that the geographic distributions of *Aedes aegypti* and yellow fever are the same. Not till a quarter of a century later, after Stokes, Bower and

1. Bennett, Byron L.; Baker, Fred C., and Sellards, Andrew Watson: *Science* **88**: 410 (Oct. 28) 1938.

Hudson (1928) had shown that rhesus monkeys are susceptible to yellow fever, was it practicable to make adequate tests of other species. Two other subtropical species of mosquitoes were then shown to be equally efficient vectors of yellow fever, while a third subtropical species would occasionally transmit the disease in an attenuated form.

The question was raised as early as 1904 by J. B. Smith<sup>2</sup> of Trenton, N. J., whether or not the disease could be transmitted by the common northern mosquito. An attempt was not made to answer this question, however, until 1935, when Baker established a colony of *Aedes triseriatus* in his local insectary at Cornell University and sent specimens to the Harvard Medical School for transmission tests. The species bred by Baker is common from Maine to Florida and has been identified as far west as Montana.

At the Harvard Medical School thirty-five of these northern mosquitoes were allowed to feed on a monkey dying from yellow fever. After this feeding the mosquitoes were kept for seventeen days at a temperature of 28 C. (82.4 F.) and six of the seven survivors then allowed to bite a healthy monkey. After an incubation period of six days this monkey showed a transient febrile reaction (104 F.) lasting about twenty-four hours, after which it was without demonstrable symptoms for nearly a month. The monkey, however, died on the thirty-sixth day. Necropsy showed typical appearances of yellow fever.

Bennett and his co-workers have recently repeated this test with four additional monkeys. After being bitten by presumably infected neo-arctic mosquitoes, the four monkeys showed no febrile reaction. Two of them, however, died of yellow fever between the tenth and the thirteenth day. Control intracerebral inoculation of mice with mosquito emulsions showed that 60 per cent of the mosquitoes which had bitten an infected monkey fifteen days previously were carriers of yellow fever. It is nevertheless suggestive that the two monkeys which developed no symptoms had been bitten by mosquitoes kept from fourteen to fifteen days at 28 C., while the two monkeys which died had been bitten by mosquitoes incubated at 37 C. (98.6 F.).

When subtropical mosquitoes are used to infect monkeys with yellow fever there is a usual incubation period of from three to four days, followed by a sharp rise in temperature (104 to 105 F.) lasting from thirty-six to forty-eight hours. This is followed by subnormal temperature and collapse, death almost invariably taking place on the fifth or sixth day. The prolonged incubation period in the Harvard tests, therefore, suggests that the virus of yellow fever is attenuated in the bodies of neo-arctic mosquitoes. Of particular hygienic interest is the evidence that temperature plays an important part

in determining vector infectivity. Somewhat analogous temperature effects have been described for subtropical mosquitoes. This result suggests that low temperature rather than the absence of available insect carriers is the main factor limiting the spread of yellow fever in northern states.

## Current Comment

### TRAFFIC IN OPIUM

With the submission of the report of the Advisory Committee on Traffic in Opium and Other Dangerous Drugs<sup>1</sup> to the Council of the League of Nations, a new and important stage of work in the suppression of the abuse of narcotics appears to have begun. The committee framed a definite statement of the essential principles which might serve as a basis for a future convention on limitation and indicated that this future convention will render possible a final suppression of the use of opium for smoking in countries or territories where the practice is still authorized. Its main purpose will be to develop appropriate measures for a gradual reduction of the quantities of raw opium required for the manufacture of prepared opium. The report of the preparatory committee, which was adopted by the advisory committee, stated as a premise that opium is being produced in quantities far in excess of recognized world requirements. The world requirements of raw opium for purposes recognized in the convention should be ascertained by a system of government estimates similar to that applied under the previous limitation convention. In furnishing such estimates governments would have to state not only the quantities but also the qualities (morphine content) of the opium required. A definite quantitative limit should be fixed annually for the amount of raw opium to be produced by each country. This should be achieved by estimating the requirements and by government agreements not to exceed the estimates in their imports. Estimates of production and requirements should be examined by an international control authority which should have the task of allocating to each producing country on the basis of the estimates the annual quantities to be produced and exported. Furthermore, the convention should consider the methods of regulating stocks of raw opium to be kept in producing and consuming countries and provisions should be made for safeguarding the carrying out of the convention by means of national control. The application of the convention, as in the case of the limitation convention in 1931, should be supervised by an international body entrusted with such powers and duties as shall be specified in the convention. The success of the limitation convention in 1931 has been such as to indicate that this properly international problem of control is now approaching its final phase. While the United States is not a signatory of the League, it has been represented at all the conventions and has ratified all but the 1925 convention for opium control.

# ORGANIZATION SECTION

## COUNCIL ON MEDICAL EDUCATION AND HOSPITALS

The Council on Medical Education and Hospitals held its usual fall meeting in Chicago on December 4.

### REPORT ON PROGRAM OF FEBRUARY CONFERENCE

A report was made on the program for the next Annual Congress on Medical Education and Licensure to be held in Chicago in February.

### VISITS TO MEDICAL SCHOOLS

Reports of recent visits to medical schools were also considered. The Council noted the progress that had been made toward the preparation of a final report on the survey of medical schools which it is planned to publish in the spring or early summer.

### ACTION ON UNIVERSITY OF ARKANSAS MEDICAL SCHOOL

The University of Arkansas School of Medicine, by vote of the Council, is now listed as being on probation.

### ACTION ON VERMONT AND VIRGINIA COLLEGES

A review of conditions at the University of Vermont College of Medicine and the Medical College of Virginia was postponed until the next academic year.

### APPROVAL OF CERTIFYING BOARD IN ANESTHESIOLOGY

The American Board of Anesthesiology was approved.

### COOPERATION WITH CERTIFYING BOARD IN RADIOLOGY

A plan of cooperation which had been prepared by the Council and the American Board of Radiology was endorsed and it was recommended that other special examining boards be invited to participate in similar plans.

### CONSIDERATION OF HOSPITALS

The usual lists of hospitals desiring registration, intern approval and residency approval were presented and acted on.

### CONFERENCE ON COOK COUNTY HOSPITAL

Representatives of the staff of the Cook County Hospital were informed that, while there has been no change in the status of the Cook County Hospital, the Council appreciates the efforts which have been made to improve conditions and the willingness of the executive committee to cooperate with the Council in further efforts to make it an outstanding center of medical education.

### ACTION ON HOSPITALS APPROVED FOR INTERNSHIP

The Essentials of a Hospital Approved for the Training of Interns were amended so that after Jan. 1, 1940, a minimum of thirty-six necropsies a year will be required, and for a service having 2,000 annual admissions at least three interns will be deemed necessary.

### APPROVED RESIDENCIES

The scope of the Council's list of approved residencies was broadened and its title hereafter will be "Approved Residencies and Fellowships."

The Council voted that at least one year's training in general surgery should be a prerequisite for approved residencies or fellowships in such subdivisions of surgery as urology, orthopedic and thoracic surgery.

### MEETING WITH ADVISORY COMMITTEE

The Council on Medical Education and Hospitals conferred also with a newly appointed advisory committee. Those present included Drs. Ray Lyman Wilbur, J. H. Musser, Fred Moore, Reginald Fitz, Charles Gordon Heyd, Frank H. Lahey, William D. Cutter, Malcolm T. MacEachern, John R. Neal, Charles B. Pinkham, William P. Wherry, Herman G. Weiskotten, Rock Sleyster, Olin West, Morris Fishbein, Oswald N. Andersen, Fritjof H. Arestad, Hamilton H. Anderson and Mr. Homer F. Sanger.

WILLIAM D. CUTTER, M.D., Secretary.

## AMERICAN MEDICAL ASSOCIATION STUDY OF MEDICAL CARE

### Jefferson County, Alabama

The Jefferson County Medical Society report of the Survey of the Need and Supply of Medical Care is so complete in all its phases as to deserve special mention.

Jefferson County occupies an area of 1,124 square miles in the north central portion of Alabama. It has an estimated population of 477,100, of which approximately 38 per cent are Negroes. The city of Birmingham has a population of 289,700, and the two next largest cities, Bessemer and Fairfield, have populations of 21,700 and 13,300 respectively. In addition there are seven other cities and villages with populations varying from 466 to 7,341. Jefferson County is largely dominated by the iron and steel industries.

The county medical society not only conducted the study in an exceptionally thorough manner but also made a careful and scholarly analysis of the facts. The

report of the study and the recommendations filled 131 typewritten pages, which have been permanently bound for future reference. The summary and conclusions which follow are given exactly as they were prepared by the committee in charge of the study.

### SUMMARIZED REPORT OF THE SURVEY

The following report covers the more important details, determined by actual survey, and summarizes the original 140 page report prepared by the secretary of the committee. The procedures used for the collection of data were those outlined by the American Medical Association. The information obtained includes and supplements that requested by the American Medical Association and is intended to furnish the society with all the pertinent facts relative to the problems involved.

The sources of information which form the basis of this study are given in table 1.

The fact that only 58 per cent of all physicians and dentists answered their questionnaires, as compared to 100 per cent of the various agencies, does not necessarily indicate that the professions were the least

interested in the survey. The difference is partially accounted for by the manner in which the data were collected. When agencies did not respond by mail the proper parties were interviewed personally. This procedure was not possible with physicians and dentists. Because of their large number, contact was entirely by mail and by telephone.

Due credit should be given to the various welfare, relief and health agencies for their willingness to furnish all available information; of all the groups approached they appeared to be the most interested and most cooperative.

#### PHYSICIANS AND DENTISTS

There are in Jefferson County 438 physicians and 148 dentists engaged in active practice. This excludes those who have retired and a few who are completely occupied in administrative capacities. There is one physician for each 1,089 of the general population.

The nature of the data requested of members of both professions precludes the presentation of actual figures; only estimates are available, though it is felt (after checking the reports made by physicians with those from the various institutions and agencies) that these estimates are conservative and probably considerably understate the facts.

Returns were received as shown in table 2.

If the data, based on actual reports of 64.4 per cent of all practicing physicians and 40.5 per cent of all practicing dentists, are truly representative of medical and dental practice in this locality, the figures obtained can appropriately be extended to include all those who have not returned their questionnaire. When such figures are combined with data obtained from all the various institutions and agencies, the total charity load may be conservatively estimated as in table 3.

Approximately one half of charity patients applied directly to physicians and dentists and received free treatment, while one half were treated in hospitals and clinics. These figures definitely indicate that the charity

load of physicians in home and office practice is fully as great as the charity load carried by physicians in all institutional practice, including hospitals, outpatient departments and clinics of all the various agencies.

Besides the incalculable number of hours given by physicians in the medical care of hospital inpatients, they devoted an estimate of 41,000 hours to the free care of ambulatory cases in outpatient departments and dispensaries and to preventive medical care in various health centers and clinics. For all this they received nothing except nominal compensation for approximately 5 per cent of their time.

Seventy-four per cent of physicians perform preventive medical services. Of ninety physicians reporting on the amount of preventive medical work done for charity and for pay, 37 per cent stated that they did no charity work, 25 per cent reported that less than 50 per cent of their preventive medical services were for charity, while 38 per cent reported that more than 50 per cent of such work was for charity.

Compensation for preventive medical services (in significant amounts) is made by only two organizations. The health department paid \$4,054 to forty-two physicians and \$948 to eighteen dentists for 2,054 hours of work in health centers. The Anti-Tuberculosis Association paid \$1,305 to five physicians for clinic sessions. With minor exceptions all other medical and preventive medical services were performed by physicians without remuneration.

#### DENTISTS

The participation of dentists in this study has been disappointing. Questionnaires were sent to all 148, but only 40.5 per cent replied. Many of these were incomplete.

The amount of charity work done by dentists cannot be estimated very closely, but on the basis of individual

TABLE 3.—*Total Charity Load of All Physicians and Dentists*

	Patients	
	Number	Distribution

Total .....	153	100

information it appears that the charity load of the individual physician is more than twice that of the individual dentist. The charity load of all physicians is probably more than eight times that carried by all dentists.

#### AVAILABILITY OF MEDICAL CARE

Of physicians and dentists commenting on the availability of medical care, 80 per cent knew of no instance in which persons had been unable to obtain medical,

dental or hospital care. Twenty per cent reported instances in which persons were unable to obtain such care.

The majority of physicians expressed some opinion regarding the adequacy or inadequacy of present methods and facilities for providing medical care. The

Metropolitan Life .....	5	2,012	0
Total .....	208	29,911	55.7

interpretation of these opinions has been difficult, and for that reason the data should be regarded as only an approximation.

The most frequent comment made was an expression of the need for a part pay clinic and hospital for the low income group which would also provide for the specialized services such as x-ray and biopsy free or at reduced rates.

## HOSPITALS

There are in Jefferson County fourteen hospitals with a total capacity of 1,689 beds, or 3.5 beds per thousand of the population.

Hospital rates vary from a low of \$1.50 a day for ward beds to a high of \$10 a day for private rooms. These rates are not excessive.

Of a total of 41,000 patients cared for in local hospitals, 31 per cent were for charity. The average stay of pay patients in hospitals was 8.7 days, as compared to an average stay of 12 days for charity patients.

The load of charity hospital services was carried as shown in table 5.

Six hospitals operate outpatient departments or associated clinics and served 37,710 persons, of whom 18,081 were charity patients.

As regards inpatient services, most pay hospitals report the rejection of patients because of their inability to pay or because beds were not available. The number of persons rejected cannot be determined.

The County Hospital reports a need for 100 additional beds. All hospitals emphasize the need of providing for hospitalization of contagious diseases. As regards sanatorium beds for the treatment of tuberculosis there are now available for white persons only 72 per cent, and for Negroes only 5 per cent of those considered necessary for this county.

Group hospital insurance seems to have been an important factor in Jefferson County in making hospital care available to the general public, though there is no indication that it has served to lighten the load

of charity hospital service. Of an estimated number of 62,375 persons carrying hospital insurance providing complete or practically complete coverage, approximately 11,000 carry insurance through the Hospital Service Corporation and the remainder through various industrial arrangements.

## NURSING SERVICES

Services performed by the various nursing organizations may be summarized as in table 6.

The number of private duty nurses available through the nurses' registry, though small, appears adequate to serve those patients who can afford to pay for nursing services. There is one public health nurse for each 12,000 of the general population; accepted standards for good public health practice call for one nurse for each 2,500 of the population.

Nurses comment on the lack of provision for hospitalization of cases of contagious disease. Of a total of 3,653 contagious disease patients receiving some nursing care, 3 per cent were served by private duty nurses, the remainder by public health and visiting nurses. Approximately 65 per cent of the 22,187 individuals served by the health department nurses were clients of the department of public welfare.

## HEALTH DEPARTMENT

Time does not permit an adequate summation of the work of the health department; furthermore, the general familiarity of the profession with the nature of its services makes this unnecessary.

In 1937 the health department employed 113 persons in maintaining the following services: administration, records and vital statistics, laboratories, health education, food control, sanitation, child and maternal hygiene, public health nursing, and school health education.

Table 7 briefly outlines some of the major activities.

TABLE 7.—Major Activities of Health Department

1.	8,627 births and 5,892 deaths recorded 8,110 transcripts issued
2.	73,866 specimens (of value in the diagnosis of infectious diseases) were examined for physicians of Jefferson County 10,143 specimens of food and 3,087 samples of water from public water supplies examined The commercial value of this laboratory work by conservative estimate amounted to 1½ times the cost of operating the entire health department
3.	5,049 inspections of retail food establishments 171,758 veterinary inspections of animals slaughtered at packing houses 15,554 dairy inspections 230,000 pounds of food condemned 27,622 improvements effected
4.	22,685 sanitary inspections of public and private premises 6,670 nuisances abated 1,596 toilet facilities improved or installed 631 cases of contagious diseases isolated 1,732 contacts quarantined
5.	954 public lectures given 1,132 moving pictures shown 52 radio talks given
6.	53,804 visits by nurses to 22,187 persons 12 maternal and child hygiene, and 4 dental clinics operated serving 8,070 persons who were seen by physicians or dentists

The health department is well organized and its activities are well conducted. Its usefulness, however, is greatly limited through lack of funds. The committee does not feel that a detailed report of the financial needs of the health department is pertinent to the present discussion except to state (1) that expenditures for public health in Jefferson County are not only small but fall more than 50 per cent short of the

requirements for a minimum program which may be consistent with safety and (2) that, while state subsidy to Jefferson County for county health work has increased in recent years, such subsidy on a per capita basis is still only 50 per cent of that allocated to other counties and should be increased.

A detailed discussion of the financial status of the health department has been submitted to the board of censors for its information and for such action as it may deem appropriate.

#### PRIVATE AND GOVERNMENTAL WELFARE, RELIEF AND UNOFFICIAL HEALTH AGENCIES

Of the thirty-seven agencies included in the category of private and governmental welfare, relief and unofficial health agencies, twenty-seven are financed by the community chest. Fourteen agencies either arrange for or furnish medical or dental care. Ten arrange for or provide care in physicians' or dentists' offices, while six arrange for or provide care in the home. Eleven agencies attempt to arrange for hospital services, though none should be considered as actually doing so as most hospitals have their own rules for accepting patients regardless of who may refer them for care. Seven agencies provide limited supplies of drugs.

Clinics are maintained as shown in table 8.

TABLE 8.—Clinics Maintained by Agencies

	Number of Visits *
Department of public welfare.....	1,890
Antituberculosis association .....	3,911
Fresh air farm.....	350
Juvenile court .....	1,500
Trinity community house.....	3,131
Total clinic visits.....	10,782

\* All numbers are estimated

Those agencies which operate clinics render a direct service. Most others seek medical care for their clientele by requesting physicians to render services without charge or by utilizing other charity institutions. The more important charity organizations which carry the great bulk of the charity load, and which are most commonly utilized by all the various agencies are the antituberculosis association, children's hospital and clinic, county hospital and clinic and the health centers of the health department.

It is estimated that approximately 7,100 persons were provided with care through direct efforts of all the various social agencies. They report a total of 1,270 persons for whom care could not be obtained; 1,100 of these were reported by the department of public welfare.

#### DEPARTMENT OF PUBLIC WELFARE

Because of its importance, special mention should be made of the department of public welfare. During the year 1937 the department averaged approximately 4,000 families who received financial assistance. These were made up of those over 65 years of age, households with children under 16 where there was no employable head of the family, and those entirely physically or mentally handicapped to earn a living. The case load represents a high percentage of individuals having physical disabilities.

Because of limited funds, appropriations for prescriptions, drugs, visits of physicians and medical appliances must all be kept on the same inadequate basis as the

monthly grants, which in their entirety are below the subsistence level for food.

A total of \$1,308 of city-county funds was expended for maintenance of a medical office in Birmingham, while \$1,585 in city-county funds was expended in maintaining a clinic in Bessemer; to the latter the Works Progress Administration added \$3,911. The total expenditures by the department of public welfare (from all sources) was \$6,804 for the medical care of the sick in 4,000 families. Of this total physicians received \$289.

Provisions for home and office visits of physicians are for emergency cases only and are entirely inadequate to meet the medical needs of persons on relief. The clinic facilities in Bessemer are, of course, available only to persons on relief who live in that district. Under the circumstances it is not surprising that medical care was not obtained for an estimated number of 1,100 persons.

#### SCHOOLS

There are six school systems with a total enrolment of 103,000. Two systems with approximately half this enrolment provide for medical and dental inspection of pupils. In the other four systems the health status of the child rests with the teacher or public health nurse, and arrangements for medical examination and care must be made through family physicians, clinics, health centers or other means as circumstances permit. One failure of existing school health programs lies in the inability to make medical examinations at regular intervals. As a result many defects which might be corrected through private or public means are never discovered. Furthermore, facilities are not available to follow up properly those children who need corrections in an effort to see that they are obtained.

#### MEDICAL CARE IN INDUSTRIES

Forty-nine establishments provide medical care of employees only in case of accidents. Twenty-two firms furnish complete medical care for approximately 190,000 employees and dependents. With minor exceptions medical care provided by industries is judged to be adequate. Of the employees of all companies which provide complete medical care, 92.3 per cent have free choice of physician and may elect medical care by fee deduction or in two instances may accept such services from the company without cost to themselves. Approximately 2,900 individuals are given medical care through mutual benefit associations or by similar arrangements.

#### PHARMACISTS

The reports from pharmacists are not sufficiently reliable to merit attention. Of interest, however, was their comment regarding the needs for medical care.

Of seventy-nine pharmacists making comment, four considered present facilities for medical care adequate; three made miscellaneous comment. Seventy-two favored a change in methods or facilities for providing medical care and thirty-two of these favored some unspecified form of governmental control, four advocated utilization of the community chest, while thirty-six offered no plan or suggestion.

#### NEEDS FOR MEDICAL CARE

Physicians and dentists in home, office and institutional practice, on very conservative estimate, cared for from 100,000 to 116,000 charity patients. Despite this tremendous charity load carried by the professions, it

appears that present facilities are inadequate and that many needy persons were unable to obtain medical care.

The actual number of persons unable to obtain such care cannot be determined with accuracy. What is perhaps more important than arriving at the actual number is an appreciation of those circumstances under which medical care is ordinarily not available.

There is no great difference of opinion between physicians, dentists and the various social and health agencies as to the inadequacies of facilities and the present circumstances under which medical care is not available. These inadequacies are expressed in the following recommendations made by these groups in answering questionnaires.

The most commonly expressed opinions of physicians, dentists and the various social agencies for additional needs are:

1. Part pay clinics and hospital for the low income group.
2. Dental clinics (performing preventive and restorative services for the indigent).
3. Provisions for home care of the indigent and follow-up care of those discharged from hospitals. Also ambulance service to charity hospitals for the critically ill.
4. Better facilities for the treatment of syphilis.
5. Provision for hospitalization of contagious disease cases.
6. More sanatorium beds for the treatment of tuberculosis.
7. More adequate provision for the care of transients and nonresidents.
8. Increased facilities at Hillman Hospital and clinic, larger social service staff.
9. Increased facilities of health department.

The various agencies also expressed the following opinions which were not commonly expressed by members of the professions. Need for:

1. Payment through public funds of physicians and dentists for home, office and institutional care of the indigent.
2. A centralized social service bureau to serve all agencies.
3. Provision for health examination of persons over 12 years of age.

4. Psychiatric clinics; more adequate hospital provisions by the state for the care of mental cases.
5. More adequate provision for drugs, teeth, eyeglasses and so on.
6. Child guidance clinic.
7. Ear clinic for the treatment and prevention of hearing defects.
8. Better organization of medical resources.

#### RECOMMENDATIONS

1. The committee endorses in principle a part pay hospital and clinic for the low income group, which group it designates as those whose income level is just above that established by the Hillman Hospital in its "basic guide for determining indigency."

2. In order to differentiate between charity, part-pay and pay patients the committee feels that it will be essential to establish a dignified and efficient business bureau with a social service department to investigate thoroughly the financial status of patients. This should be a centralized service functioning for all charity and part-pay institutions including the Hillman Hospital and clinic, department of public welfare, health department and others.

3. The committee recognizes the total inadequacy for hospital care of cases of contagious disease (both pay and indigent) and feels that some provision should be made.

4. The committee feels that local appropriations for public health in Jefferson County are not only small but fall 50 per cent short of the requirements for a minimum program. Furthermore, state subsidy to Jefferson County for county health work, on a per capita basis, is only 50 per cent of that granted to other counties and should be increased.

[The remainder of the report deals with a local hospital and a special "Proposed Plan for the Medical Care of the Indigent and Low Income Groups."]

## OFFICIAL NOTES

### JUDGE PROCTOR OVERRULES MOTION TO QUASH SECOND SUBPENA

Following Judge James M. Proctor's quashing of two thirds of a subpoena requiring the American Medical Association to present before the Special Grand Jury certain records, some extending as far back as sixteen years, the Department of Justice revised the subpoena. The revised subpoena would command to bring: All . . . documentary communications and all reports or memoranda . . . containing statements with respect to any action or policy taken or adopted or considered or proposed to be taken or adopted by or on behalf of the A. M. A. or of any medical society or association affiliated with the A. M. A., or of any hospital, in opposition to group medical practice or to the provision of medical care on a periodic prepayment basis, drawn up, sent or received from Jan. 1, 1935, to Nov. 20, 1938, by certain officials at the headquarters of the association, its judicial council, its bureau of investigation, and any other official employee of the association who, according to the present knowledge of the officials, drew up, sent or received such papers.

Counsel for the American Medical Association argued before the court that the present order was so broad that it was void. Counsel also quoted a decision by Justice Holmes of the United States Supreme Court to the effect that it was "contrary to first principles of justice" for a grand jury to go deeply into records of a corporation "in the hope that something will turn up."

In overruling the motion to quash the revised subpoena, Justice Proctor is reported to have set down the following memorandum opinion:

A recent subpoena duces tecum to the American Medical Association was partially quashed, as unreasonable and oppressive because of its sweeping requirements. This subpoena is intended to overcome those faults. I think it does so.

The desired papers are well identified. The periods of time to be covered by the search, although longer than the statutory period of limitation, are definitely fixed, and not necessarily unreasonable, having in mind the nature of the inquiry. The papers required, it is understood, are only those which may now be in possession of the association or its officers.

I see no reason why the association cannot comply with the subpoena without undue difficulty or hardship, if its papers have been kept under any efficient system of filing.

Counsel for the association again contend that the papers described by the subpoena are irrelevant and incompetent to the subject matter of the inquiry before the grand jury and that the matters being investigated cannot by their nature involve any violation of the Sherman Antitrust Act, in respect of its local or interstate provisions. It is therefore argued that as the investigation concerns matters of which this court would have no jurisdiction, the proceeding cannot legally form the foundation for issuance of the subpoena. It is insisted that the court should now determine these basic questions.

I cannot agree with these contentions. The virtual effect of the propositions to now pass upon the admissible quality of evidence sought for production before the grand jury, or produced before it, and to determine vital questions of jurisdiction, would be to require a close and detailed supervision by the court of the grand jury process in this investigation which, I think, can find no proper support in the historical background and development of the grand jury system, or the well established rules of criminal procedure. Moreover, the present inquiry before the special

grand jury is of an original nature. Neither the American Medical Association nor any other party has been held for action of the grand jury upon any criminal charge. The inquisition has its origin with the grand jury. There are as yet no defendants. There may never be any. Hence, at this stage of the proceedings, the association has no such status as entitles it to raise any of the vital questions now urged upon the court.

In my opinion, the motion to quash the subpoena should be overruled, and it is so ordered.

## ANNUAL CONGRESS ON MEDICAL EDUCATION AND LICENSURE

The Annual Congress of the Council on Medical Education and Hospitals of the American Medical Association will be held at the Palmer House, Chicago, Feb. 13 and 14, 1939. The Federation of State Medical Boards of the United States will participate in the Congress. The program follows:

### MONDAY MORNING, FEBRUARY 13

*The Protection of the Public Through the Activities of the Council on Medical Education and Hospitals*

Ray Lyman Wilbur, M.D., LL.D., Chairman, Stanford University, Calif.

(Subject to be Announced)

James B. Conant, Ph.D., President, Harvard University, Cambridge, Mass.

*The Organization and Subject Matter of General Education*

Robert Maynard Hutchins, LL.B., President, University of Chicago.

(Subject to be Announced)

Walter F. Donaldson, M.D., Secretary, Medical Society of the State of Pennsylvania, Pittsburgh.

*Canadian Experiments in Medical Economics*

T. C. Routley, M.D., LL.D., General Secretary, Canadian Medical Association, Toronto, Ont.

### MONDAY AFTERNOON, FEBRUARY 13

*The South as Testing Ground for the Regional Approach to Public Health and Public Welfare*

Howard W. Odum, LL.D., Director, Institute for Research in Social Science, University of North Carolina, Chapel Hill.

### SYMPOSIUM ON THE SMALL HOSPITAL

*Organization and Management of the Small Hospital*

Malcolm T. MacEachern, M.D., Associate Director, American College of Surgeons, Chicago.

*The Community Hospital*

Barry C. Smith, General Director, The Commonwealth Fund, New York.

*The Planning and Organization of the Small Hospital*

William Henry Walsh, M.D., Consultant Specialist on Hospitals, Chicago.

*The Construction of the Small Hospital*

Carl A. Erikson of the firm of Schmidt, Garden and Erikson, Architects, Chicago.

### TUESDAY MORNING, FEBRUARY 14

*The Program of the National Committee for Mental Hygiene*

Clarence M. Hincks, M.D., General Director, National Committee for Mental Hygiene, New York.

*Federal Support of Professional Education*

Dean Lewis, M.D., Surgeon-in-Chief, Johns Hopkins Hospital, Baltimore.

*Fundamentals of Industrial Hygiene*

T. Lyle Hazlett, M.D., Professor of Industrial Hygiene, University of Pittsburgh School of Medicine and Medical Director, Westinghouse Electric and Manufacturing Company, Pittsburgh.

*The Relation of Anesthesiology to Medical Education*

Ralph M. Waters, M.D., Department of Anesthesia, University of Wisconsin Medical School, Madison.

*Tenure of Members of the Faculty in Schools of Medicine*

Anton J. Carlson, Ph.D., Frank P. Hixon Distinguished Service Professor of Physiology, University of Chicago.

### TUESDAY NOON, FEBRUARY 14

Luncheon meeting, to which all those attending the Congress are invited to attend:

Address: *What the Undergraduate College Should Give the Future Doctor*

William Mather Lewis, LL.D., President, Lafayette College, Easton, Pa.

### MONDAY EVENING, FEBRUARY 13

#### FEDERATION DINNER

(Program to be announced later.)

### TUESDAY, FEBRUARY 14

THE FEDERATION OF STATE MEDICAL BOARDS OF THE  
UNITED STATES

(Program to be announced later.)

## THE ST. LOUIS SESSION

### Special Exhibits on Fractures and on Anesthesia in the Scientific Exhibit

The Committee on Scientific Exhibit of the Board of Trustees has announced two special features for the St. Louis session, May 15-19, 1939.

The Special Exhibit on Fractures will be presented as a former annual sessions under the supervision of a committee the members of which are Dr. Kellogg Speed, Chicago, chairman; Dr. Frank D. Dickson, Kansas City, Mo., and Dr. Walter Estell Lee, Philadelphia.

The Special Exhibit on Anesthesia will be presented for the third year under the supervision of a committee composed of Dr. Ralph M. Waters, Madison, Wis., chairman; Dr. John S. Lundy, Rochester, Minn.; Dr. Henry S. Ruth, Philadelphia, and Dr. Philip D. Woodbridge, Boston.

Application blanks for space for other exhibits may be obtained from the Director, Scientific Exhibit, American Medical Association, 535 North Dearborn Street, Chicago.

## COMMITTEE OF PHYSICIANS MAKES NEW RELEASE

The Committee of Physicians for the Improvement of Medical Care, Inc., issued for release on December 3 a statement signed by Dr. John P. Peters and said to express the point of view of the committee in relationship to the National Health Program.

## WITNESSES BEFORE THE GRAND JURY IN WASHINGTON

The following additional witnesses are reported to have appeared before the Special Grand Jury in Washington, D. C.: Dr. Harry Clifford Loos of the Ross-Loos Medical Group, Los Angeles, and Dr. George R. Stevenson of the San Diego Beneficial Society, San Diego, Calif. Dr. Michael A. Shadid of Elk City, Okla., said to be the founder and medical director of the Farmer's Union Cooperative Hospital Association, and Mr. F. D. Kilpatrick, said to be a labor leader of Akron, Ohio, who is organizing the Summit County Cooperative Health Association.

## RADIO BROADCASTS

The fourth series of programs broadcast in dramatic form portraying fictitious but typical incidents of significance in relation to health by the American Medical Association and the National Broadcasting Company, entitled "Your Health," began Wednesday October 19 and will run consecutively for thirty-six weeks.

The program is broadcast each Wednesday over the Blue network of the National Broadcasting Company at 2 p. m. eastern standard time (1 p. m. central standard time, 12 noon mountain time, 11 a. m. Pacific time).<sup>1</sup>

These programs are broadcast on what is known in radio as a sustaining basis; that is, the time is furnished gratis by the radio network and local stations and no revenue is derived from the programs. Therefore, local stations may or may not take the program, at their discretion, except those stations which are owned and operated by the National Broadcasting Company.

The next three programs to be broadcast, together with their dates and their topics, are as follows:

- December 14. What Shall We Eat?
- December 21. Hidden Treasures in Foods.
- December 28. Good Milk, Good for You.

1. Owing to program conflicts, there will be no Chicago broadcast of the network program. Instead, a recording of the program will be broadcast over station WENR at 8 p. m. each Wednesday. This recording will be an identical rebroadcast of the network program broadcast earlier the same day.

## Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

### ARIZONA

**Plague Infection in Prairie Dogs.**—According to *Public Health Reports*, plague infection has been proved in a pool of ninety-eight fleas collected from eighteen prairie dogs (*Cynomys gunnisoni zuniensis*) shot September 27 seven miles south of St. Johns, Apache County.

### ARKANSAS

**Seventeenth Clinical Meeting.**—The Fort Smith Clinical Society held its seventeenth meeting in Fort Smith October 11 under the auspices of the clinical staffs of St. Edwards Mercy and Sparks Memorial hospitals. The speakers included:

- Dr. George V. Brindley, Temple, Texas, Treatment of Acute Perforated Appendicitis and Peptic Ulcer, Its Complications and Indications for Surgical Treatment.
- Dr. Sidney J. Wolfemann, The Advantages of Vitallium in Bone Fixation.
- Dr. William R. Brooksher, The Painful Shoulder.
- Dr. Paul M. Bassel, Temple, Thyroid Dysfunction.
- Dr. Charles T. Chamberlain, The Heart and Obesity.
- Dr. James H. Buckley, Differential Diagnosis of Acute Conjunctivitis, Iritis and Glaucoma.
- Dr. Arless A. Blair, Treatment of Underweight in Nondiabetic Individuals with Protamine Zinc Insulin.
- Dr. James W. Amis, Use of Sulfanilamide in Undulant Fever.
- Dr. Arthur F. Hoge, Factors in Mortality of Appendicitis.

### COLORADO

**Midwinter Graduate Clinics at Denver.**—The midwinter graduate clinics, sponsored by the Colorado State Medical Society, will be at the Shirley-Savoy Hotel, Denver, December 14-16. The clinics are open to all doctors of medicine in the Rocky Mountain region regardless of membership in any medical society. The guest speakers will include:

- Dr. Arlie Ray Barnes, Rochester, Minn., professor of medicine, University of Minnesota Graduate School of Medicine.
- Dr. Rollin Russell Best, Omaha, Neb., assistant professor of anatomy and surgery, University of Nebraska School of Medicine.
- Dr. Horton Ryan Casparis, Nashville, Tenn., professor of pediatrics, Vanderbilt University School of Medicine.
- Dr. Everett Dudley Plass, Iowa City, professor of obstetrics and gynecology, State University of Iowa College of Medicine.
- Dr. James E. M. Thomson, Lincoln, Neb.

### ILLINOIS

**Tri-County Meeting at Galesburg.**—The Knox County Medical Society was host at a meeting with the Henry and Warren county medical societies in Galesburg October 25. The speakers included:

- Dr. Warren H. Cole, Chicago, Hyperthyroidism.
- Dr. Claire LeRoy Straith, Detroit, First Aid Treatment of Automobile Injuries to the Face.
- Dr. William P. Murphy, Boston, The Practical Management of the Anemic Patient.
- Dr. Arthur E. Hertzler, Halstead, Kan., as the after dinner speaker, discussed "Hooks, Bobs and Sinkers." Dr. Logan Clendening, Kansas City, also spoke.

### Chicago

**Hospital News.**—The National Jewish Hospital, a tuberculosis sanatorium, Denver, has recently established an office in Chicago at 30 North La Salle Street.

**Personal.**—Dr. Paul R. Cannon, professor of pathology, University of Chicago, has been appointed a member of the Medical Fellowship Board of the National Research Council, for the period ending June 30, 1941, to complete the unexpired term of Dr. Eugene L. Opie, New York, who resigned.

**Society News.**—At a meeting of the Chicago Neurological Society October 20 the speakers were Drs. Foster Kennedy, New York, on "The Organic Background of Mind"; Victor E. Gonda, "War Neuroses," and Paul C. Bucy, "Tremor: A Consideration of Its Physiology and Abolition by Surgical Means."—The Chicago Ophthalmological Society was addressed October 24 by Drs. Samuel G. Higgins, Milwaukee, on "Ophthalmic Surgery in India" and William A. Fisher, "Senile Cataract: The Usual Method of Operating in India." Dr. Robert von der Heydt showed photographs in color of diseases of the eye.—Dr. Howard C. Taylor Jr., New York, discussed "Relationship of Hormones to the Toxemias of Pregnancy" before the Chicago Gynecological Society November 18.

—The Chicago Orthopaedic Society was addressed November 11 by Drs. Walter R. Fischer on "Fracture of the Scapula Requiring Open Reduction" (report of a case) and Wallace H. Cole, St. Paul, "Clinical Observations on the Physiology of Bone."—Dr. Gilbert J. Thomas, clinical associate professor of urology, University of Minnesota Medical School, Minneapolis, discussed "Tuberculosis of the Urological Tract" before the Chicago Medical and Urological societies at a joint meeting December 7 at the Chicago Woman's Club.

### IOWA

**Personal.**—Rev. G. T. Notson resigned as superintendent of the Methodist Hospital, Sioux City, October 21; he has held the position since the hospital was founded eighteen years ago.—Dr. Edward N. Anderson, Boston, has been appointed head football coach at the State University of Iowa, Iowa City, following his resignation from a similar position at Holy Cross College, Boston. Dr. Anderson graduated at Rush Medical College in 1930.

**Gifts to the University.**—The University of Iowa College of Medicine, Iowa City, announces a gift of \$22,500 from the John and Mary R. Markle Foundation to be spent over a two year period. Of the total, \$12,500 will provide for a continuation of the research in the department of ophthalmology under Dr. Cecil S. O'Brien on inflammatory conditions of the eye, and the remainder will be used to continue the research program in the department of pathology under Dr. Harry P. Smith, on blood clotting and the bleeding tendency.

### KENTUCKY

**Memorial to Dr. Joseph N. McCormack.**—Headquarters of the Kentucky State Medical Association and the State Department of Health of Kentucky were recently moved to a new home purchased by the state at 620 South

Home of State Medical Association and State Department of Health.

Third Street, Louisville, and dedicated October 4 during the annual meeting of the state medical association. The building has been made a permanent memorial to Dr. Joseph N. McCormack, first health officer of the state. Speakers at the dedicatory exercises were Drs. Carl C. Howard, Glasgow, former president of the state association, on "Joseph Nathaniel McCormack the Physician"; Gov. Albert B. Chandler, "Joseph Nathaniel McCormack the Public Servant," and Dr. Arthur T. McCormack, state commissioner of health, secretary of the state medical association and son of the elder McCormack. After the governor's address Miss Mary Tyler McCormack unveiled a portrait and a bronze plaque of her grandfather in the entrance hall of the building. The portrait was painted by Charles Sneed Williams, a Kentucky artist, and presented by the medical association. The plaque was the gift of the state department of health and of county health departments. Dr. Joseph N. McCormack was appointed state health officer when the state board of health was created in 1883 following an epidemic of yellow fever. He is said to have been instrumental in the passage of the state's first medical practice act and the first administrator of the law. Among other laws he sponsored were licensure laws, a vital statistics law and a bill

consolidating health agencies. He was chairman of the committee on reorganization of the American Medical Association, which functioned from 1901 to 1910. Dr. McCormack died Aug. 4, 1922, aged 75.

### MICHIGAN

**Hospital News.**—Dr. Roscoe R. Graham, Toronto, lectured at Woman's Hospital, Detroit, Hospital Day, November 9; his subject was "Some Philosophic Problems Dealing with the Relation of the Fundamental Sciences to Every Day Surgical Problems."

**Personal.**—A testimonial dinner was held in honor of Drs. Rudolph J. Maas and William P. Scott, Houghton, by the Hancock Council of the Knights of Columbus, Hancock, October 11. Dr. Maas is 83 years old and a charter member of the council; Dr. Scott is 80, a charter member of the Houghton County Medical Society and an emeritus member of the Michigan State Medical Association.

**Society News.**—A symposium on ovarian tumors was presented before the Ingham County Medical Society in Lansing October 18 by Drs. Harry M. Nelson and Donald C. Beaver, Detroit. —Dr. Evan G. Galbraith, Toledo, discussed "Pulmonary Atelectasis" before the Jackson County Medical Society in Jackson October 18. —Dr. Harry A. Towsley, Ann Arbor, addressed the Washtenaw County Medical Society October 11 on "The Acute Exanthemata." —Dr. Thurman B. Rice, Indianapolis, discussed "New Concepts in Bacteriology" before the Muskegon County Medical Society in Muskegon October 28.

**Thirteenth Annual Highland Park Clinic.**—The thirteenth annual clinic of the Highland Park Physicians Club was held November 30 at the Highland Park General Hospital. The following program was presented:

Dr. James R. Goodall, Montreal, The Placental Blood Bank.  
Dr. Eugene H. Shannon and J. A. Sullivan, M.B., Toronto, Clinical and Radiologic Aspects of Diseases of the Paranasal Sinuses.  
Dr. Russell L. Haden, Cleveland, Treatment of Anemia.  
Dr. Frederick Christopher, Evanston, Ill., Carcinoma of the Stomach.  
Dr. Martin H. Fischer, Cincinnati, Clinical Aspects of Water Turnover.

Dr. Henry A. Luce, Detroit, president of the Michigan State Medical Society, was toastmaster at the annual banquet and Malcolm W. Bingay, editorial director, *Detroit Free Press*, was the speaker.

### MISSISSIPPI

**Society News.**—The Delta Medical Society was addressed in Indianola October 12, among others, by Drs. Randolph T. Smith, Little Rock, Ark., on "Unusual Tumors of the Ovary" and Bernard H. Booth, Drew, "Atrabrine in Malaria." —A symposium on diseases of nutrition was presented before the Issaquena-Sharkey-Warren Counties Medical Society in Vicksburg October 11 by Drs. Henry B. Goodman, Anguilla; George W. Gaines, Tallulah, La.; Hugh H. Johnston, Vicksburg, and Walter H. Scudder, Mayersville.

### NEW JERSEY

**Cooperative Child Guidance Program in Paterson.**—A child guidance program centered about the neuropsychiatric clinic of the Paterson General Hospital has been developed in cooperation with interested agencies. The plan is to have a discussion with the specific agency that can best aid each child, with suggestions for treatment. A monthly conference is planned with each agency to study the development of the child, who is seen frequently at the clinic during the period of study. The general hospital gives its facilities to the project, and the social agencies contribute the social workers and social facilities. Among the agencies that are cooperating are the Family Welfare Society, probation authorities, criminal courts, police department, schools, churches, Church Mission Help, North Jersey Training School, the Young Men's Christian Association, Young Women's Christian Association, the Young Men's Hebrew Association and Young Women's Hebrew Association. Dr. Theodore Rothman is director of the project.

**Society News.**—At a recent meeting of the Monmouth County Medical Society in Asbury Park the speakers were Drs. Harold A. Kazmann, Long Branch, on "Early Symptoms of Gastrointestinal Carcinoma"; Louis F. Albright, Spring Lake, "Treatment of Pernicious Anemia," and Carlos A. Pons, Asbury Park, "Rocky Mountain Spotted Fever." —A symposium on pain low in the back was presented before the Passaic County Medical Society in Passaic October 13 by Drs. Arthur Bruce Gill, Philadelphia; William J. Mixer, Boston, and Samuel Kleinberg, New York. —Dr. Frederic E. Elliott, Brooklyn, addressed the Essex County Medical Society, Newark, November 10, on "Medical Expense Insur-

ance." —Dr. Jesse G. M. Bullowa, New York, addressed the Bergen County Medical Society, Bergen Pines, November 8, on "The Pneumonias." —Dr. Samuel A. Loewenberg, Philadelphia, addressed the Academy of Medicine of Northern New Jersey, Newark, November 17 on "Endocrine Disturbances and Present Day Endocrine Therapy."

**Committee on Health and Welfare Appointed.**—Gov. A. Harry Moore has appointed a special committee to "follow up and determine applications to the needs of New Jersey of certain of the considerations brought out at the Washington Conference in July." It will be known as the New Jersey Committee on Health and Welfare. Robert C. Clothier, L.L.D., president of Rutgers University, New Brunswick, is general chairman of the committee, which has fifty members, including twenty-five physicians. Six technical subcommittees were created at the organization meeting in Trenton, November 16, as follows: expanded public health facilities, hospital facilities, indigent, low wage, wage loss insurance and related matters. Twelve advisory committees to the subcommittee on expanded public health facilities were also created, as follows: advisory committee at large, maternal and child health, crippled children, blind, tuberculosis, venereal disease, cancer, pneumonia, mental diseases, industrial diseases, school health and college health.

Complete, comprehensive information on all phases of medical care in New Jersey will be assembled by this committee. The fact-finding work of the committee will include determination of what physical equipment, facilities and services are available to satisfy the health requirements of the population, determination of the incidence of degenerative diseases, among groups in various income levels, determination of the adequacy of present sanitation measures and determination of what additional physical equipment, facilities, services and policies are required to assure that the health of the people will be safeguarded. Finally the committee will undertake to develop practical methods for remedying any conditions or deficiencies amenable to improvement. In the collection of this information, data accumulated in the surveys conducted by the Medical Society of New Jersey and its component county medical societies will be utilized for information on those phases of medical care which they cover.

The following physicians are members of the committee: Drs. William J. Carrington, Atlantic City, president of the state medical society; Fred H. Albee, New York; Walter G. Alexander, Orange; Leverett D. Bristol, Montclair; Charles V. Craster, Newark; Samuel B. English, Glen Gardner; George W. Fithian, Perth Amboy; Edward Guion, Northfield; Edgar A. Ill, Newark; Allen G. Ireland, Trenton; Henry Kessler, Newark; Joseph H. Kler, New Brunswick; Augustus H. Knight, Far Hills; Frederick P. Lee, Paterson; Julius Levy, Trenton; Jesse Lynn Mahaffey, Trenton; Stanley H. Nichols, Asbury Park; George O'Hanlon, Jersey City; Berthold S. Pollak, Secaucus; Ellen C. Potter, Trenton; Hilton S. Read, Atlantic City; Joseph M. Rector, Jersey City; Spencer T. Snedecor, Hackensack; Arthur L. Stone, Camden, and LeRoy A. Wilkes, executive officer of the state medical society.

### NEW YORK

**Rochester Academy Plans Museum.**—Plans for a medical museum in the new building of the Rochester Academy of Medicine are in process of formation. Committees have been formed to develop divisions dealing with rare books and documents, plastic and graphic arts, instrument making and historical development, and pathologic anatomy. Courses of instruction for the committees have been arranged with the librarians of the city, and the university and the Rochester Museum of Arts and Sciences is cooperating. The academy wishes especially to compile the medical history of Monroe County. Dr. Morris E. Missal is secretary of the museum committee.

### New York City

**Third Harvey Lecture.**—Dr. Eugene F. Du Bois, professor of medicine, Cornell University Medical College, will deliver the third Harvey Lecture at the New York Academy of Medicine December 15 on "Heat Loss from the Human Body."

**Faculty Appointments.**—New York Medical College and the Flower Hospital recently announced the appointment to the faculty of Dr. Reuel A. Benson to be professor of pediatrics, James W. Benjamin, Ph.D., associate professor of histology, embryo and neuroanatomy, and Dr. David Scherf, associate clinical professor of medicine. Dr. Benjamin was formerly assistant professor of zoology at Northwestern University, Chicago, and Dr. Scherf was associate professor of medicine at the University of Vienna.

**Hospital News.**—A department of anesthesiology was recently opened at the Evangelical Deaconess Hospital with Drs. Henry Trautmann and Harry J. Rosenthal in charge. —The name of the Brooklyn Home for Consumptives is to be changed to the Brooklyn Thoracic Hospital. —The Frances Schervier Hospital and Home for the Aged, built by the Sisters of the Poor of St. Francis, was dedicated November 6. It is a six story building with 404 beds. The first patients were those formerly in the St. Francis Home for Aged Incurables. —A new wing of St. Clare's Hospital was dedicated October 30.

**Society News.**—A symposium on serum therapy in pneumonia was presented at the stated meeting of the New York Academy of Medicine December 1 by Drs. Russell L. Cecil, Colin M. MacLeod and Wheelan D. Sutliff. —A program on pneumonia was presented before the Bronx County Medical Society November 16 by Drs. Ralph S. Muckenfuss, John A. Colucci, Jesse G. M. Bullova and Colin M. MacLeod. —Dr. James T. Gwathmey addressed the Bronx Pathological Society November 15 on "Pathology of Anesthesia: Tissue Changes and the Pathologic Physiology Involved in the Use of Modern Anesthetics." —A pneumonia program was presented before the Medical Society of the County of Queens November 1 by Drs. Wheelan D. Sutliff on "The New York City Pneumonia Control Program"; Carl Boettiger, Flushing, "Early Diagnosis of Pneumonia"; Rufus I. Cole, Mount Kisco, "Serum Therapy of Pneumonia," and Colin M. MacLeod, "Antipneumococcic Rabbit Serum Therapy of Pneumonia." Dr. Alfred C. Beck addressed the society October 25 on "Syphilis in Pregnancy."

### NORTH CAROLINA

**Special Society Meetings.**—Drs. Burton Haseltine, Chicago, and Grady E. Clay, Atlanta, addressed the North Carolina Eye, Ear, Nose and Throat Society at its annual meeting in Raleigh recently on "Chronic Sinus Infections" and "Arteriolar Changes in the Fundus Oculi; Convergent Strabismus in Children" respectively. Dr. Franklin C. Smith, Charlotte, was elected president; Dr. Henry H. Briggs Jr., Asheville, vice president, and Dr. Milton R. Gibson, Raleigh, reelected secretary. —Dr. Vann M. Long, Winston-Salem, was elected president of the North Carolina Urological Association at its annual meeting in Greensboro October 31. Dr. John Mason Hundley Jr., Baltimore, was the guest speaker at the annual dinner, on "Physiologic and Pathologic Observations on the Urinary Tract During Pregnancy."

### OKLAHOMA

**New Health Officers.**—Dr. Frederick E. Dargatz, formerly of Kinsley, Kan., has been appointed director of the health unit of Ardmore to succeed Dr. Richard M. Parish. —Dr. Reed Wolfe, Sulphur, has been appointed health superintendent of Choctaw County.

**Society News.**—Drs. Carroll M. Pounders, Oklahoma City, and James William Finch, Hobart, addressed the Western Oklahoma Medical Society at a meeting in Hobart recently on "Rheumatic Fever in Childhood" and "Etiology of Nausea and Vomiting of Pregnancy" respectively. —Drs. J. Wendall Mercer and Evans E. Talley, Enid, addressed the Woods-Alfalfa County Medical Society, Cherokee, recently on "Prenatal Disturbances, Symptoms and Treatment" and "The Thyroid" respectively. —Drs. Rufus Q. Goodwin and Frederick Redding Hood, Oklahoma City, addressed the Garfield County Medical Society, Enid, October 27, on "Treatment of Pneumonia with Serum Therapy" and "Cardiac Irregularities" respectively.

### PENNSYLVANIA

**Program on Exceptional Child.**—The child research clinic of the Woods Schools, Langhorne, presented its fifth institute on the exceptional child October 18. The following program was given:

Dr. Eugenia S. K. Cameron, Baltimore, Factors in the Etiology of Psychoses in Early Adolescence.  
Dr. Lawson G. Lowrey, New York, Problems of Aggression and Hostility in the Exceptional Child.  
Dr. Josephine H. Kenyon, New York, Stimulation of Growth in Short Children.  
Edgar A. Doll, Ph.D., Vineland, N. J., Social Maturation.  
May Ayres Burgess, Ph.D., New York, Height Charts in Growth Studies.

Dr. Frederick H. Allen, Philadelphia, presided at the morning session and Miles Murphy, Ph.D., Philadelphia, at the afternoon session.

### Philadelphia

**Plans for Third Postgraduate Institute.**—The Philadelphia County Medical Society will sponsor its third annual Postgraduate Institute March 13-17, 1939, on the subjects "Blood Dyscrasias" and "Metabolic Disorders." There will be eighty-six clinical lectures with open forum discussion of each topic. Dr. Rufus S. Reeves is director of the institute. Sessions will be held at the Bellevue-Stratford Hotel.

**Society News.**—Dr. William Bates addressed the Philadelphia Clinical Association November 15 on "Pseudosurgical Abdomen." —At a meeting of the Philadelphia Neurological Association November 18 the speakers included Drs. Lester S. King, Princeton, N. J., on "Equine Encephalomyelitis" and George D. Gammon, "The Muscular Weakness of Family Periodic Paralysis." —Members of the department of diseases of children, Columbia University College of Physicians and Surgeons, New York, addressed the Philadelphia Pediatric Society November 8. Among the speakers were Drs. John P. Caffey, on "Syphilis of the Skeleton in Early Infancy; the Nonspecificity of Many of the Roentgen Changes," and Richard L. Day, "Effect of Sleep on Insensible Perspiration in Infants and Children."

**Women Sponsor Cancer Forum.**—The Women's Auxiliary of the Lankenau Hospital Research Institute and district 1 of the Pennsylvania State Nurses' Association sponsored a cancer forum November 29-30 at the Bellevue-Stratford. The guest speakers included:

Dr. William B. Wartman, Cleveland, Highlights in the History of Cancer.  
Dr. James J. Durrett, U. S. Food and Drug Administration, Washington, D. C., Cancer Quacks.  
Dr. Martha Edith MacBride-Dexter, Harrisburg, state secretary of health, Activities of the Pennsylvania Department of Health with Special Reference to Cancer.  
Dr. William Carpenter MacCarthy, Rochester, Minn., How the Pathologist Aids in Combating Cancer.  
Major Julia C. Stimson, Army Nurse Corps, U. S. Army, retired, New York, The Nurses' Responsibility in Prevention and Early Recognition of Cancer.

### Pittsburgh

**Hospital News.**—Montefiore Hospital held its annual "scientific day" November 12 with Dr. Samuel A. Levine, Boston, as the guest speaker and clinician. Dr. Levine spoke in the evening on "The Value of Auscultation."

**Research on Air Filters.**—Mellon Institute announces the establishment of an industrial fellowship by the American Air Filter Company, Louisville, Ky., for the study of materials of value in the construction of filters for air conditioning systems. Frank F. Rupert, Ph.D., who has been studying air hygiene at the institute since 1935, has been appointed to the fellowship.

### RHODE ISLAND

**Hospital Building Named for Dr. Adolf Meyer.**—A new psychiatric clinic building at the State Hospital for Mental Diseases, Howard, was dedicated October 18 and named in honor of Dr. Adolf Meyer, Henry Phipps professor of psychiatry, Johns Hopkins University School of Medicine, Baltimore. The semiannual meeting of the New England Society of Psychiatry was held in the afternoon following the dedication. Dr. Meyer and Dr. John E. Donley, Providence, made addresses at the dedication exercises. An appropriate plaque was installed in the lobby of the building and Dr. Seth F. H. Howes, superintendent of the hospital, presented to Dr. Meyer a scroll commemorating the occasion. In the afternoon Dr. Meyer addressed the psychiatric society on "The Psychiatric Hospital in a Progressive Health Program." In the evening a dinner was held in honor of Dr. Meyer at the University Club in Providence, under the auspices of the Rhode Island Society for Neurology and Psychiatry. Dr. Walter C. H. Weigner, Providence, president of the society, presided and Dr. Arthur H. Ruggles, Providence, state commissioner of mental diseases, was toastmaster. The speakers included Drs. Charles Macfie Campbell, Boston, Eugen Kahn, New Haven, and Dr. Meyer. The new building is part of a \$5,000,000 building program at the state hospital. It has a capacity of 120 beds and was built at a cost of \$296,500.

### TENNESSEE

**Society News.**—Drs. Edward E. Reisman Jr. and Earl R. Campbell addressed the Chattanooga and Hamilton County Medical Society, Chattanooga, October 13, on "Traumatic Injuries to the Extremities" and "Wrist Injuries" respectively. —At a meeting of the Hardin-Lawrence-Lewis-Perry-Wayne Counties Medical Society in Lawrenceburg recently the speakers were Drs. William E. Boyce, Flatwoods, on "The

Hydrogen Ion Concentration of the Blood"; Jack Witherspoon, Nashville, "Duodenal Ulcer"; Thomas J. Stockard, Lawrenceburg, "Poliomyelitis," and Oval N. Bryan, Nashville, "Use of Antipneumococcic Serum in the Treatment of Pneumonia."

**Personal.**—Dr. Leonard E. Ragsdale, at one time superintendent of the State Home for the Feeble-minded, Donelson, has been appointed superintendent of the Central State Hospital for the Insane, Nashville.—Dr. Malcolm T. Tipton, Union City, has been appointed a member of the state board of medical examiners to succeed Dr. Marcus G. Spingarn, Memphis, whose term expired.—Orren W. Hyman, Ph.D., dean of the University of Tennessee College of Medicine, Memphis, received the honorary degree of doctor of laws from Southwestern University, Georgetown, Texas, recently.

### VIRGINIA

**Changes in Health Officers.**—Dr. John G. McNeil, St. Charles, has been appointed health officer of the Montgomery County health district, succeeding Dr. William W. Fuller, Christiansburg, who is studying at the Johns Hopkins University School of Hygiene and Public Health. Dr. Willard W. Griggs, St. Charles, has succeeded Dr. George R. Carpenter in the Dickenson-Wise Counties district, and Dr. Eugene B. Shepherd, Chatham, has been made health officer of the Pittsylvania County district, succeeding Dr. Benjamin Randolph Allen. Dr. Carpenter and Dr. Allen are also at Johns Hopkins. Dr. Stephen J. Beeken, Lexington, recently assistant in the Rockbridge County district, has been appointed health officer of the Russell-Tazewell district with headquarters at Richlands. He succeeds Dr. Vernon A. Turner, Richlands, who is studying at the Harvard School of Public Health.

### WISCONSIN

**Society News.**—Dr. Karl C. Wold, St. Paul, addressed the Pierce-St. Croix County Medical Society, Baldwin, October 20, on "Common Disorders of the Eye: Their Diagnosis and Treatment."—Dr. Charles B. Puestow, Chicago, addressed the Winnebago County Medical Society, Oshkosh, October 6 on "Preoperative and Postoperative Care."

**Hospital News.**—St. Vincent Hospital, Green Bay, celebrated the fiftieth anniversary of its opening October 12-13 with a dinner for the staff, city and county officials and open house.—Milwaukee Hospital, Milwaukee, celebrated its seventy-fifth anniversary during the week of October 30; from a twenty bed institution it has grown to a capacity of 263.

**Personal.**—Dr. Glenford L. Bellis has retired as superintendent of the Muirdale Sanatorium and Blue Mound Preventorium, Wauwatosa. Physicians and employees of the sanatorium gave a testimonial banquet to Dr. Bellis October 13 and presented him with a plaque.—Dr. Albert J. Randall, assistant director of health in Kenosha, has been appointed director to succeed Dr. Gustave Windesheim, who retired October 15.

### GENERAL

**Massengill Firm Fined.**—Dr. Samuel E. Massengill, Bristol, Tenn., president of the S. E. Massengill Chemical Company, pleaded guilty in the federal court at Kansas City October 19 on sixty-two counts covering shipments of Elixir of Sulfanilamide-Massengill made from the Kansas City plant of the company. He was fined \$9,300. In federal court at Greenville, Tenn., October 3 the defendant's counsel pleaded guilty on 112 counts and was sentenced to pay a fine of \$150 for each count, making a total of \$16,800 (THE JOURNAL, October 22, p. 1567).

**Special Society Elections.**—Dr. Edward S. Godfrey Jr., New York state commissioner of health, Albany, was chosen president-elect of the American Public Health Association at the annual meeting in Kansas City, October 25-29, and Abel Wolman, Dr. Eng., Johns Hopkins University School of Hygiene and Public Health, Baltimore, was installed as president. The following were elected vice presidents: Drs. Albert Grant Fleming, Montreal, Canada; Leonides Andreu Almazan, chief, department of health, Mexico, and Edwin H. Schorer, Kansas City. The 1939 meeting will be in Pittsburgh.—Dr. Louis L. Williams Jr., U. S. Public Health Service, Washington, D. C., was chosen president-elect of the American Society of Tropical Medicine at the annual meeting in Oklahoma City November 15-18. Dr. Alfred C. Reed, San Francisco, became president; Drs. Sterling S. Cook, Portsmouth, Va., and E. Harold Hinman, Wilson Dam, Ala., were elected vice president and secretary respectively.—Dr. James K. McGregor, Hamilton, Ont., was chosen president-elect of the American Association for the Study of Goiter at the recent annual meeting

during the International Goiter Conference in Washington, D. C. Dr. Frank B. Dorsey Jr., Keokuk, Iowa, became president and Dr. Claude J. Hunt, Kansas City, was elected vice president. Dr. William Blair Mosser, Kane, Pa., is corresponding secretary and Dr. George C. Shivers, Colorado Springs, recording secretary.—Dr. Paul A. O'Leary, Rochester, Minn., was elected president of the American Academy of Dermatology and Syphilology at the annual meeting in St. Louis in November. Dr. Harther L. Keim, Detroit, was elected vice president and Dr. Earl D. Osborne, Buffalo, secretary. The 1939 meeting will be held in Philadelphia.

**Fellowships in Medical Sciences.**—The National Research Council announces that the following fellows, appointed by the medical fellowship board, have begun their work:

Dr. Louis K. Alpert, Chicago, at the Rockefeller Institute for Medical Research, New York.  
Philip P. Cohen, Ph.D., Madison, Wis., at the University of Sheffield, England.  
Thomas H. Davies, Ph.D., Baltimore, at the California Institute of Technology, Pasadena.  
Dr. Carl L. Larson, Butte, Mont., at the University of Rochester (N. Y.).  
Dr. Arthur P. Richardson, San Francisco, at John Hopkins University, Baltimore.  
Jane A. Russell, Ph.D., Berkeley, Calif., at Yale University, New Haven, Conn.  
Wilfred W. Westerfeld, Ph.D., St. Louis, at Oxford University, Oxford, England.

**Symposium on Mental Health.**—The section on medical sciences of the American Association for the Advancement of Science will conduct a symposium on mental health at the annual Christmas meeting in Richmond, Va., December 28-30. Sessions will be held at the Commonwealth Club except the final general session, which will be at the Mosque. Contributions to the symposium will be printed in advance and the sessions will be devoted to discussion of them. One topic will be discussed at each session. Dr. Charles Macfie Campbell, professor of psychiatry, Harvard University Medical School, Boston, will give the summary and address at the general session. Among the contributions listed in the program are:

Dr. Charles P. Fitzpatrick, Providence, R. I., Facilities for Research.  
E. Morton Jellinek, M.Ed., Worcester, Mass., Function of Biometric Methodology in Psychiatric Research.  
Dr. George Gilbert Smith, Boston, Relationship of Birth Control to Mental Conditions.  
Dr. John D. Reichard, Ellis Island, N. Y., Immigration and the Mental Health of Communities.  
Carney Landis, Ph.D., New York, and James Page, Ph.D., Rochester, N. Y., Magnitude of the Problem of Mental Disease.  
Dr. Helen Flanders Dunbar, New York, Bearing of Emotional Factors on Social-Health Programs Dealing with Economic Disability.  
Edward Sapir, Ph.D., New Haven, Conn., Psychiatric and Cultural Pitfalls in the Business of Getting a Living.  
Charles C. Limburg, Ph.D., Lexington, Ky., Community Differences and Mental Health.  
Dr. Winfred Overholser, Washington, D. C., Psychiatric Expert Testimony.  
Dr. George S. Stevenson, New York, Psychiatry in a Community.  
Dr. Edward A. Strecker, Philadelphia, Undergraduate Instruction in Psychiatry in the United States and Canada.

Dr. Thomas M. Rivers, New York, is chairman of the section on medical sciences and Malcolm H. Soule, Sc.D., Ann Arbor, Mich., is secretary. Dr. Walter L. Treadway of the U. S. Public Health Service, Lexington, Ky., is chairman of the program committee.

## Government Services

### Government Dedicates Narcotic Hospital at Fort Worth

The U. S. Public Health Service hospital for narcotic addicts at Fort Worth, Texas, the second of its type, was dedicated October 28. Dr. Thomas Parran, surgeon general, U. S. Public Health Service, made the dedicatory address and other speakers were Dr. Lawrence Kolb, assistant surgeon general in charge of the division of mental hygiene of the public health service, and James V. Bennett, director of the bureau of prisons of the department of justice. The new institution covers 1,400 acres and cost \$4,000,000. It includes an administration building, a clinical ward building, a maximum custody ward, residences for personnel and maintenance structures. A prolonged treatment building for advanced cases of addiction will be ready in 1939. The first narcotic hospital at Fort Worth unit places less emphasis on custodial features, such as high gates and walls and inclosed courts. Passed Assistant Surgeon William F. Ossenfort of the service, medical director of the new hospital, is a graduate of Washington University School of Medicine, St. Louis.

## Foreign Letters

### LONDON

(From Our Regular Correspondent)

Nov. 12, 1938.

#### Cardio-Omentopexy

The important advance of Mr. Laurence O'Shaughnessy in introducing the operation of cardio-omentopexy to provide collateral circulation in cases of cardiac ischemia, with its resultant angina pectoris, has been described in previous letters. The report of the Royal College of Surgeons for 1937-1938 contains a note on the experimental and clinical work performed by him during the year in conjunction with Dr. Slome, on which they have a paper in preparation. They have demonstrated that vascular continuity between a graft and the coronary tree can be obtained without the use of myocardial sutures, provided a special aleuronat preparation is used. Early experiences with the danger and difficulty of inserting stitches into a friable and degenerated myocardium make this an important technical advance. They have also shown that a graft applied to an adherent pericardium can still be effective. The importance of this observation was emphasized at a recent operation when they encountered pericardial adhesions at the site of a fairly recent infarct. Some of the experiments of Lezius, who first showed that the lung can rapidly form vascular adhesions with the heart after incision of the parietal pericardium, were repeated and his results confirmed.

The electrocardiogram of the grafted heart shows specific changes. Mr. O'Shaughnessy and Dr. Slome have records collected from several patients over a period of a year and more. An attempt to correlate their observations with electrocardiograms of grafted animals is still in progress. They have found that acute coronary occlusion may complicate the results of operation, and an experimental investigation of its treatment has become pressing.

The results in a series of twenty patients with cardiac ischemia operated on in the Lambeth cardiovascular clinic were published early in 1938. The survivors in this series and of more recent operations are still under observation. Patients who have survived the operation for one year and in some cases for two years continue to be active. One death from heart failure has occurred in the group, and if deaths from heart failure continue to be rare or absent as the group becomes larger, this fact alone will be significant.

#### Casualties of Air Raids

Speaking at the council dinner of the British Medical Association, the Right Hon. Walter Elliot, minister of health, said that on June 1 he took over the responsibility of organizing the emergency hospital system against the possibility of air raids. A survey had already been made of 3,000 hospitals and institutions and 400,000 beds. Hospital officers were appointed in every region of the country except London and asked to prepare schemes for the best utilization of hospital accommodation. At the same time a committee of medical experts presided over by Sir Charles Wilson, dean of St. Mary's Hospital, was appointed to consider the provision for London casualties, the type of hospital to be utilized for them and the extent to which peace time patients could be moved. In early August contact was established with every hospital throughout the country and they were asked to clear as many beds as possible on receiving warning from the government that an emergency had arisen. In September the international situation was so acute that plans had to be concentrated for immediate operation. Large orders were placed for hospital requirements, including surgical equipment for hospitals not then capable of dealing with casualties. On the last day of August every hospital officer was given instructions to accelerate plans

for clearing hospital beds, and 150,000 beds, with medical attendance and nursing complete, would have been available within twenty-four hours. That was only the beginning. Representatives of thirty-four of the larger London hospitals to be evacuated and representatives from the receiving areas were received by the ministry. Ambulances, both train and automobile, were organized. By September 24 the necessary number of stretchers were distributed to each hospital. From that moment the hospital evacuation scheme could have been put into operation within twenty-four hours of the warning. The crisis passed, but that was not the end of the possible emergencies. The hospitals were now being registered where surgical facilities could be improved.

### PARIS

(From Our Regular Correspondent)

Nov. 12, 1938.

#### Paris Physicians Protest Against Social Insurance

The abuse of free medical care by the public hospitals and dispensaries and the illegal extension of the original function of the social insurance authorities are arousing the French medical profession to make a vigorous campaign to put an end to a movement which renders it difficult for physicians to earn a living. In the notice sent out by the association of physicians in the department of the Seine, in which Paris is situated, for a meeting to be held Nov. 4, 1938, the following plea was made for a full attendance:

1. It is becoming more and more difficult, in fact almost impossible, to practice in Paris and the adjacent areas.
2. The public hospitals and dispensaries, which are not subjected to the excessively high taxes which physicians must pay, are doing all they can to give free medical attention without any inquiry as to the ability of the sick to pay. Such institutions should treat only indigents.
3. The social insurance organization was created to insure the worker earning up to a certain sum annually, now 30,000 francs, so that he might be able to pay for medical care. Instead of limiting their activities to this commendable objective, the social insurance authorities have begun to make serious inroads on the work of private practitioners by attempting to organize facilities for treating the insured worker. Every effort is being made to turn the insured from specialists and general practitioners by urging them to enter public hospitals or receive treatment at the many public dispensaries.
4. The situation has become so acute that the time has arrived for a more energetic campaign against these abuses, which make it impossible for a physician, after many years of preparation, to compete with the tendency toward state medicine.

#### Foreign Physicians Being Naturalized in France

Not only is there a marked increase in the number of first year medical students at all the medical schools here, but there is a fear that the government is giving permission to become naturalized to more physicians coming to France than there is room for in the profession. The number of foreign physicians who wish to practice here rose from four in 1935 to ninety-four in 1937. The Armbruster law, passed in 1933, requires all physicians of foreign birth not only to be naturalized but to serve the same length of time in the army or navy as those born in France or its colonies. At a recent meeting of the association which has charge of public relations for the French medical profession, the secretary, Dr. Cibrie, stated that permission to become naturalized is being too easily granted by the authorities, without adequate investigation of the past records of the applicants. An information bureau has been opened by the Confederation of Medical Syndicates, as the central organization is termed, to furnish the authorities with all data as to whether or not an applicant for naturalization is worthy of remaining in France.

### Antitoxin-Toxoid Treatment of Diphtheria and Tetanus

The question of whether the transitory passive immunity following the injection of diphtheria or tetanus antitoxin can be converted into a more permanent active immunity by simultaneous use of the diphtheria or tetanus toxoid has been the subject of papers at recent meetings of the Société médicale des hôpitaux of Paris. At the July 22 meeting the results of the combined use of the diphtheria antitoxin and the toxin were reported from three Paris hospitals. In the first paper Drs. René Martin and his co-workers stated that they had given the treatment to twelve children with diphtheria. A subcutaneous injection of 0.1 cc. of the toxoid was followed twenty minutes later by a single large dose of antitoxin. Forty-eight hours later a second injection, varying from 0.3 to 0.5 cc. of the toxoid, was given. Subsequently the toxoid in gradually increasing doses, beginning with 1 cc., was given every five days. Aside from slight febrile and local reactions after the first and second injections of the toxoid, no ill effects were noted. These reactions seem to be of an antigenic and not of an allergic character.

The titer of the antitoxin in the blood was measured at frequent intervals after the first injection of the toxoid. These determinations showed that the passive immunity conferred by the antitoxin does not interfere with the development by the toxoid of an active immunity in the majority of cases. Patients who had a well marked incipient immunity before the antitoxin was given showed a striking rise in the titer of the antitoxin in the blood after injection of the toxoid. Patients who failed to show any antidiphtheria immunity before being given the antitoxin showed a distinct but less marked increase in the titer of the antitoxin in the blood after injection of the toxoid. These observations appear to confirm the theory of Prof. Gaston Ramon that the brief transitory passive immunity conferred by the diphtheria antitoxin is succeeded by an active immunity which is more stable and of longer duration when the toxoid also is given.

#### OBSERVATIONS ON SOLDIERS

In a second paper, Drs. Solier and Jaulmes reported their observations on eleven soldiers with diphtheria at the large Val-de-Grace Hospital. A diphtheria toxoid with a titer of 150 units per cubic centimeter was used. A dose of 0.1 cc. was given the first day and was followed one hour later by a massive single dose of diphtheria antitoxin. This was followed by the injection at regular intervals during the remainder of the hospitalization of gradually increasing doses of the diphtheria toxoid. The eleven patients all recovered, no reaction of any importance following the use of the diphtheria toxoid being noted. Estimations of the titer of diphtheria antitoxin in the blood serum of the eleven patients were made over a period of six months. These estimations showed the constant presence of a titer of antitoxin in the blood serum adequate to protect the patient against a recurrence of the infection. This observation shows the advantage of the use of Ramon's combined antitoxin and toxoid administration as applied to a collectivity such as an army.

#### OBSERVATIONS ON CHILDREN

In a third paper, Drs. Darré and Lafaille reported their results with thirty-three children who had diphtheria. Of these, four had a malignant type, four had a severe form and sixteen had moderately severe form. In the last-named group, although some were not seen until the third or fourth day, no paralysis of the soft palate followed. In the seven with severe involvement, in spite of extensive formation of false membrane, no complications were noted. In all four with the malignant type an early paralysis of the soft palate was observed but there were no other sequels, such as generalized paralysis or cardiac and respiratory symptoms. These four children all recovered,

although in one the prognosis appeared very unfavorable. There were no deaths in the other twenty-nine cases.

The mode of administration in the thirty-three cases was as follows: On admission the child was given an injection in the left subscapular region of 0.1 cc. of a purified diphtheria toxoid with a titer of 150 units to the cubic centimeter. A half hour later a single massive dose of antitoxin, varying from 18,000 to 40,000 units according to the severity of the attack, was injected in the abdominal region. Forty-eight hours later, 0.5 cc. of the toxoid was injected, and then at intervals of five days two injections of toxoid, 1 cc. and 2 cc. respectively, were given. Before every injection the titer of antitoxin in the blood serum was determined, and it showed results which agreed with those of the observers cited.

In the discussion of these papers Dr. Marquetry failed to share the enthusiasm which the others had expressed regarding this new treatment of diphtheria. The number of patients thus far treated is too small to permit definite conclusions to be drawn. At present he believed that the antitoxin-toxoid treatment greatly complicated matters.

### Brucellosis Congress

The subject selected by the Federation of Medical Societies of Northern Africa for its next congress is brucellosis. The meeting will be held at Oran, Algeria, in April 1939. The titles of the papers to be read are epidemiology of the brucelloses, bacteriologic identification, clinical forms, medical and surgical complications, treatment, animal brucellosis and prophylaxis in Tunis, Algeria and Morocco. Those wishing to attend the congress are asked to write to Dr. René Solal, 16 Boulevard Joffre, Oran, Algeria.

### Many Physicians in French Parliament

There are a relatively large number of physicians in both the Chamber of Deputies and the Senate. At a recent election for senators in thirty departments, twelve physicians were elected or reelected. Many important laws affecting the medical profession have had their origin in bills submitted by physicians who were deputies or senators.

### Death of Proctologist

Many American proctologists have visited the clinics of Dr. Raoul Bensaude of Paris, who died during October. His book on rectosigmoidoscopy is used all over the world, and before his death he had just completed the fourth volume of a series on diseases of the intestine.

### BERLIN

(From Our Regular Correspondent)

Nov. 1, 1938.

### Genealogic Survey of the German People

A new comprehensive type of genealogic survey based on previous investigation has been ordered by the minister. This survey is basically intended to include the entire population, although it will at first concern itself with those groups among which eugenic and racial hygienic measures have been or are being carried on according to recognized legal stipulations. The new survey will represent in general an assembly of all data which may be relevant to the evaluation of the eugenic and racial status of familial groups and their members. Health officials record the data with regard to individual persons in a genealogic card catalogue and the data on familial groups in a special registry. The registration place for each person is the health bureau having jurisdiction over his place of birth. A table of the familial group has been devised which forms the matrix of a genealogic axis about which all particular data with regard to a group are assembled. Such a table is created for each family. The sum of familial data go to make up the registers of familial groups. The tables are to be compiled for as great a number of families as possible in order to promote the genealogic survey of the entire population.

### New Regulations for Nursing

The national government has just issued a "Statute for Regulation of Nursing," which contains certain innovations. In Germany, as elsewhere, a crisis in nursing has long existed. This crisis, according to a statement emanating from professional sources, expresses itself most clearly in a lack of a new generation of persons willing to enter Christian nursing orders. This state of affairs has been exacerbated by the spiritual degeneration incident to the Nazi revolution. The acute shortage of younger persons in the religious nursing organizations has been paralleled by a stronger influx into the Nazi Sisterhood as well as into the German Red Cross, the latter group having been reorganized along Nazi lines. Nevertheless, the need for a greater number of younger nurses is still urgent; the number of training schools is likewise inadequate. These circumstances underlie promulgation of the new decree, which now, for the first time, envisages a nationwide regulation of the nursing profession. Public hospitals are now compelled to establish and maintain nurses' training schools either at their own expense or, if necessity requires, with the aid of public funds. These schools must enroll the young apprentice sisters according to the maximal quotas prescribed by law for each institution. The training of male nurses is similarly regulated. The director of a nurses' training school must be a physician and the assistant director either a nursing sister or a male nurse. These officers must be morally and politically reliable (Nazi style) as well as of German blood. Like qualifications are demanded of matriculants in the nursing schools. Hereafter the course of training will cover only one and one-half years, instead of two years, as formerly. Professional training must be predominantly practical; the theoretical courses must be in part conducted by physicians. An official handbook serves as the basis of instruction. The curriculum must include an introduction to "weltanschaulichen," ethical principles of the nursing profession and, besides, regular classes in bodily hygiene. Compulsory insurance against personal injury and sickness is stipulated. Since October 1 only persons who hold special official licenses have been permitted to practice the nursing profession. The license is issued to a person who has passed the examination, but at first the nursing activities of the graduate are restricted to a public hospital. Only after a year of nursing in such an institution is the licensee certified for nursing outside a public hospital. A license may be revoked if the essential prerequisites of its granting become nullified, for example on the basis of political and moral unreliability, bodily or mental handicap or addiction to alcohol or narcotic drugs. Jews may practice nursing only among other Jews and in Jewish hospitals. Jewish nurses can receive training only in Jewish schools.

The new law represents a great improvement over the previous situation, in which the practice of the nursing profession was open to all and without government recognition.

### Psoriasis

Julius Mayr, professor of dermatology at Munich, has published a study of the problem of the heritability of psoriasis vulgaris. The author found analogous cases in a pair of enzymotic female twins. It is significant that the disease was manifested earlier and assumed a severer form in the twin whose bodily weight was the greater. From study of a family tree which comprised records of fifty-eight members over four generations, it was ascertained that psoriasis had been present in the generation of the grandparents but had reappeared only in the twins (four siblings of the latter were unaffected). The parent generation exhibited no signs of psoriasis. Also from the genealogic table it was ascertained that the penetrating power of psoriasis is often extremely slight, since the disease was found to be much less extensively distributed than would have been the case in a dominant hereditary transmission. It appears noteworthy that in this family diabetes was present in three members on the same (maternal) side.

### Prof. Karl Sudhoff Is Dead

Prof. Karl Sudhoff, former ordinarius of the history of medicine at Leipzig University, died shortly before completion of his eighty-fifth year. A country practitioner for some thirty years, Sudhoff in 1905 left the small town in which he had worked to accept appointment as extraordinarius in the newly founded chair of medical history at Leipzig. This chair was the first of its kind in Germany. Sudhoff's publications on medical history attracted widespread attention. While engaged in general practice, he had earned a notable reputation as a Paracelsus scholar. At Leipzig he grew to be the leading medical historian. His research on manuscripts represented surprisingly rich contributions to our knowledge of medieval medicine. In 1903, in collaboration with the chemist Kahlbaum, Sudhoff founded the German Society of Medical and Natural Scientific History. At Leipzig he established and headed the first regular Institute of Medical History. In the following decades Sudhoff's activities, and especially his writings, brought modern medicohistorical research into high regard. Worthy of note in addition to the mentioned paracelsian studies is Sudhoff's pioneer work in medieval balneology and the history of syphilis. The guiding principle of Sudhoff's thought was constantly to serve the present by study of the past. In 1919 he became ordinarius and his retirement took place in 1925. Later, after his successor, Prof. H. E. Sigerist, had quit Leipzig for Baltimore, Sudhoff resumed professorial activity and directorship of the institute. His eightieth birthday found him still vigorously active in this capacity. Sudhoff was greatly honored for his services. Among other things he was doctor honoris causa of philosophy and veterinary medicine and honorary member of the Royal Society of Medicine of London and of the Society of Medical History of Chicago. The German Society of Medical History changed its style to "Sudhoff-Gesellschaft" in his honor. Sudhoff was the extremely active editor of "Classics of Medicine," "Studies in Medical History" and the journal *Archiv für Geschichte der Medizin*, among other publications.

### The Institute of Thermology

The Warmte Stichting (institute of thermology) foundation has commemorated its tenth anniversary. This foundation, in addition to its usual function of inspection, has examined such problems as desiccation of grain, the ventilation of stables, the radiation of hearths and stoves, the conduction of heat in building materials and buildings, and central heating. New methods of measurement have been developed by the institute; among others a method for gaging the ventilation of dwelling rooms and work rooms, and a thermo-electric instrument for measurement of humidity. The foundation's chief of technical service took an active part in the work of the commission appointed to study atmospheric conditions in the buildings constructed by the Royal Institute of Engineers.

### Combined Immunization Against Scarlatina and Diphtheria

In North Holland province, since 1930, tens of thousands of children have submitted to combined immunization against scarlatina and diphtheria, effected by a mixture of diphtheria antitoxin and scarlatina antitoxin. This immunization has favorably influenced the incidence of diphtheria and also, to a lesser degree, the incidence of scarlatina. In 1937, among 25,018 inoculated children from 6 to 13 years of age, the scarlatina morbidity was 15.1:10,000; among 29,127 children not immunized the rate was 50.1:10,000. Inoculation did not cause any serious complications, although local reactions occurred sometimes accompanied by a scarlatiniform exanthem and slight elevation of temperature.

Oct. 29, 1938.

## Air Raid Experiment in a Basement

For the protection of air raid refugees, the Industrial Hygiene Society, the planning board of the home office and the city protection association at Kanda joined September 12 in making a three hour experiment in the basement of the Hundredth Bank in the middle of Tokyo. Seventy adults participated, including forty-two examiners and inspectors. The directors were Shigeyuki Kitaura and Kentaro Kuroyanagi, engineers. The department of architecture and the sanitation department of the Tokyo Imperial University participated. The army and the navy sent its inspectors. The aim was to observe the ventilation when many refugees were shut up in a closed place and to learn how long they could remain. The basement was provided with every protection against poison gas, and every crevice was sealed up with gum tape. The twenty-eight examinees, of whom the oldest was 64 and the youngest 18, were all male. After a physical examination they went down into the basement. They wrote down on cards at any time they wanted what they felt and thought. The room was 25 square meters in area and 2.6 meters in height. As the examinees were closely packed in this room the temperature and humidity were reported every half hour to the office on the first floor. At 1:35 p. m. the temperature was 28.1 C. (82.5 F.) and the humidity 86, but they both gradually rose, and at 4:35 the former was 32.6 C. (90.7 F.) and the latter 99. At 4:18 a man of 48 found that he was unable to remain, while all the rest stood firm for the three hours without any notable ill effects. Further stay was thought to be dangerous. Detailed reports are to be made public in the near future.

## Military Medicine

Surgeon Major General Koizumi, chief of the bureau of military medicine, made a report on recent progress at a meeting of the Kyushu Medical Society. He defined military medicine in its broad sense as quite different from the military medicine based on fighting, or individual treatment. Medicine which aims to treat individuals has checked the progress and development of military medicine. In its broad sense military medicine requires public health establishments, social supplementary training and suitable surroundings for every profession and business. Universal strengthening of the nation's health ought to be considered. In the narrow sense, military medicine aims to strengthen the soldier's physical constitution. Medicine ought not to confine itself within its old circles but should dare to embrace researches into the social life. The speaker went on to the problem of how to have better efficiency in fighting, how to obtain a large quantity of pure water to supply soldiers, how to provide soldiers with ample food in the field and how to reeducate the wounded to furnish them with new occupations. He added that in the past war the number of the ill at the front was three or four to one wounded in fighting, but that in the present war the number has been reduced to 1.5 with illness to one wounded. This fact shows the development of military medicine.

## Reopening of Peking University

The old Peking University in North China was compelled to close because of the war between China and Japan. It is now making preparations for resuming lectures, and a great change in the organization is going to be realized with aid from Japan. The medical department, which was opened recently, has as its dean Prof. Dr. Hisomu Nagai, who had been dean in the Formosa Medical College after retirement from Tokyo Imperial University, and twelve professors and assistant professors, all Japanese, have been appointed. The agricultural department was opened in September with many Japanese professors. An engineering department will be attached to the

university, also with many Japanese on its staff. The total number of Japanese professors is estimated to be over sixty. The course is to be four years, and postgraduate courses will be founded to train graduates who wish to be specialists.

## All Medical Men Must Register

The government has enacted a new law for the registration of persons who are connected with medicine. The law requires reports from every physician, dentist, pharmacist and nurse who lives in Japan or in its territory abroad, including the South Sea islands. Once in every four years, on August 1, such persons are obliged to present a report concerning their ability to serve the government. Those who fail to make returns are liable to a penalty of 500 yen (\$135). Some of the chief articles in the report concern military service, condition of health, possibility of engaging in the national mobilization and family relations. About 59,700 physicians, 21,000 dentists, 26,700 chemists and 110,000 nurses are expected to make reports.

## Dr. Irisawa Is Dead

Dr. Tatsukichi Irisawa, honorary professor of Tokyo Imperial University, died at the age of 74 at the university hospital of pyelitis. After graduating in 1889 he was sent by the government to Germany to study for several years. In 1902 he was appointed to the chair of internal medicine. In 1921 he was made dean of the medical department and at the same time was appointed chief of court physicians. He held the latter position until 1927, when he resigned. In his will he asked his followers to dissect his body. He especially requested that his brain be dissected, for he had suffered from infantile paralysis at the age of 2.

## Marriages

MARTIN A. COMPTON, 1st Lieut., M. C., U. S. Army, Fort Benjamin Harrison, Ind., to Miss Bertha Mac La Fara of North Vernon, October 22.

DONALD T. HUGHSON, Madison, Conn., to Dr. FRANCES KATHRYN GRAMLING of Milwaukee, September 28.

WILLIAM C. SHEEIAN, Stevens Point, Wis., to Miss Antoinette M. Doolan of Madison, October 22.

MAURICE A. F. HARDGROVE, Milwaukee, to Miss Olive Van Susteren of Little Chute, Wis., September 3.

ARTHUR L. REINARDY, Stevens Point, Wis., to Miss Helen Steingraeber of Kewaunee, September 17.

JOHN P. HARNEY, Hartsdale, N. Y., to Miss Phyllis M. Hannemann of New York, August 6.

OTTO E. TOENHART, Sheboygan, Wis., to Miss Bessie McIntyre of Madison, September 17.

ALBERTI FRASER LAPSLEY, Badin, N. C., to Miss Mary Jane Hall of Roanoke, Va., November 12.

HOWARD J. LANEY, Prescott, Wis., to Miss Katherine V. May of Madison in September.

EUGENE E. BURZYNSKI, Laona, Wis., to Miss Helen Krieger of Milwaukee, September 30.

THOMAS PAINE SALTIEL, Chicago, to Miss Gene Sternberg of New York, November 14.

HAROLD L. MILLER to Miss Margaret Marian Plonsker, both of Milwaukee, August 10.

MYRON T. MCCORMACK to Miss Edna Lucille Purtell, both of Milwaukee, September 3.

CHARLES QUIRICO DE LUCA to Miss Cecilia McCarthy, both of Philadelphia, October 29.

LEO A. JORDAN to Miss Adrienne L. Bates, both of Saginaw, Mich., September 22.

HARVEY G. E. MALLOW to Miss Alice Dierker, both of Watertown, Wis., July 21.

HUGH A. CUNNINGHAM to Miss Mildred Owen, both of Milwaukee, August 28.

FRANK A. MAJKA to Miss Ruth N. Ryan, both of Pueblo, Colo., October 24.

WILLIAM F. RAGAN, Milwaukee, to Miss Myrtle Halverson, September 24.

## Deaths

**Addinell Hewson** • Philadelphia; Jefferson Medical College of Philadelphia, 1879; emeritus professor of anatomy, Medico-Chirurgical College, Graduate School of Medicine, University of Pennsylvania; formerly professor of anatomy and histology at Temple University School of Medicine; at various times assistant professor of anatomy and demonstrator at his alma mater; fellow of the American College of Surgeons and member of the American Association of Anatomists; served on the staff of the Episcopal Hospital, where he was dispensary surgeon from 1887 to 1904; surgeon to St. Timothy's Hospital, now known as the Memorial Hospital, from 1894 to 1928; aged 83; died, October 27, at his home in Bryn Mawr, Pa.

**Leo Melville Crafts** • Minneapolis; Harvard University Medical School, Boston, 1890; an Affiliate Fellow of the American Medical Association; professor of nervous and mental diseases, Medical Department of Hamline University, 1893-1908, and dean, 1897-1903; past president of the Minnesota Neurological Society; served during the World War; delegate to the International Congress of Medicine, London, 1913, and the International Neurological Congress, Berne, Switzerland, 1931; on the staffs of the Minneapolis General, St. Mary's, St. Barnabas, Asbury, Swedish, Eitel and Maternity hospitals; aged 74; died, September 22, of coronary thrombosis.

**Frank Sidle Lynn** • Baltimore; University of Maryland School of Medicine, Baltimore, 1907; professor of clinical surgery at his alma mater; member of the American Surgical Association and the Southern Surgical Association; formerly vice president of the Medical and Chirurgical Faculty of Maryland; fellow of the American College of Surgeons; visiting surgeon to the University, Mercy, Franklin Square and Bon Secours hospitals, Hospital for Women of Maryland and Baltimore City Hospitals; aged 54; died, September 26, of cerebral hemorrhage.

**John Clement Heisler** • Philadelphia; University of Pennsylvania Department of Medicine, Philadelphia, 1887; since 1930 emeritus professor of anatomy at his alma mater and professor of anatomy, 1916-1930; professor of anatomy at the Medico-Chirurgical College of Philadelphia, 1898-1916; member of the American Association of Anatomists; author of "Textbook of Embryology," 1898, 1901 and 1907, and "Textbook of Practical Anatomy," 1912; aged 76; died, September 9, of chronic myocarditis.

**John Bruce McCreary**, Shippensburg, Pa.; University of Maryland School of Medicine, Baltimore, 1892; member of the Medical Society of the State of Pennsylvania; formerly deputy secretary of health for Pennsylvania and chief of the bureau of child health; served during the World War; past president of the American Association of School Physicians; on the staff of the Chambersburg (Pa.) Hospital; aged 68; died, September 13, of coronary embolism.

**John Martin Julius Raunick**, Harrisburg, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1900; member of the Medical Society of the State of Pennsylvania; health officer; past president of the Dauphin County Medical Society; past president of the Harrisburg Academy of Medicine; formerly on the staff of the Harrisburg Hospital; aged 63; died, September 15, of arteriosclerosis.

**William Woodburn** • Boone, Iowa; Hahnemann Medical College and Hospital, Chicago, 1888; past president and secretary of the Boone County Medical Society; health officer; president of the Iowa Public Health Association; on the staff of the Boone County Hospital; aged 78; died, September 2, of cerebral hemorrhage with right hemiplegia.

**Myers Worman Horner**, Mount Pleasant, Pa.; Jefferson Medical College of Philadelphia, 1896; past president and secretary of the Westmoreland County Medical Society; formerly deputy coroner; at one time member of the school board; on the staff of the Henry Clay Frick Memorial Hospital; aged 67; died, September 26, of multiple neuritis.

**Willard Henry Pierce**, Greenfield, Mass.; University of Vermont College of Medicine, Burlington, 1885; member of the Massachusetts Medical Society; formerly on the staff of the Franklin County Public Hospital; aged 72; died, September 24, in Montague of chronic myocarditis, empyema and bronchopneumonia.

**Frank Winfield Laidlaw** • Middletown, N. Y.; Jefferson Medical College of Philadelphia, 1903; district health officer; member of the consultant staffs of the Horton Memorial Hospital, Middletown, Monticello (N. Y.) Hospital and the Maimonides Hospital, Liberty; aged 62; died, September 20.

**Isaac N. McComb**, Brillion, Wis.; Chicago Medical College, 1877; member of the State Medical Society of Wisconsin; health officer in Brillion for many years and on numerous village and county boards; formerly member of the state legislature; aged 87; died, September 27, of arteriosclerosis.

**George Erastus Goodrich** • Phoenix, Ariz.; Rush Medical College, Chicago, 1906; fellow of the American College of Surgeons; on the staffs of St. Joseph's and Good Samaritan hospitals; surgeon to St. Luke's Hospital; aged 59; died, September 3, in Los Angeles of heart disease.

**Lawrence Ewald Lepper** • Los Angeles; University of California Medical Department, San Francisco, 1912; fellow of the American College of Surgeons; served during the World War; on the staff of the California Hospital; aged 51; died, September 18, of heart disease.

**Albert George Gorczyca** • Elizabeth, N. J.; Georgetown University School of Medicine, Washington, D. C., 1929; aged 32; on the staffs of the Alexian Brothers Hospital and St. Elizabeth Hospital, where he died, September 24, of hypertrophic cirrhosis of the liver.

**Frank Robert Smith Sr.**, Baltimore; University of Maryland School of Medicine, Baltimore, 1891; member of the Medical and Chirurgical Faculty of Maryland; formerly associate of medicine, Johns Hopkins University; aged 82; died, September 26, of heart disease.

**Raynauld Dobson Richman** • Hartford, Conn.; University of Buffalo School of Medicine, 1908; served in the World War; for many years connected with the Aetna Life Insurance Company; aged 53; died, September 16, of hypertensive cardiovascular renal disease.

**Kennard J. French**, Factoryville, Pa.; Kentucky School of Medicine, Louisville, 1905; member of the Medical Society of the State of Pennsylvania; aged 75; died, September 26, in the Moses Taylor Hospital, Scranton, of arteriosclerosis and hypostatic pneumonia.

**Robert Alexander Simpson**, Washington, Ga.; College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1884; member of the Medical Association of Georgia; aged 79; died, September 24, of carcinoma of the prostate.

**Elmer Hinckley Heath** • Buffalo; Harvard University Medical School, Boston, 1923; assistant dean and associate professor of medicine, University of Buffalo School of Medicine; aged 43; died, September 23, of hypertension and arteriosclerosis.

**Benjamin M. Watkins** • Derry, Pa.; Jefferson Medical College of Philadelphia, 1909; bank president; aged 54; on the staff of the Latrobe (Pa.) Hospital, where he died, September 30, of pulmonary embolism following injuries received in a fall.

**Cloud M. Jackson**, Elizabethtown, Ind.; Hospital College of Medicine, Louisville, 1903; member of the Indiana State Medical Association; served during the World War; formerly county coroner; aged 61; died, September 29, of myocarditis.

**Robert Lee Frisbie** • Rhinelander, Wis.; Marion-Sims College of Medicine, St. Louis, 1894; for many years deputy state health officer; aged 68; died, September 17, in the Wisconsin General Hospital, Madison, of cerebral arteriosclerosis.

**Ray H. Johnson** • Buffalo; University of Buffalo School of Medicine, 1893; fellow of the American College of Surgeons; aged 70; on the staff of the Deaconess Hospital, where he died, September 17, of fracture of the skull resulting from a fall.

**James Aubrey Lippincott**, Nice, France; Jefferson Medical College of Philadelphia, 1873; member of the Medical Society of the State of Pennsylvania and the American Ophthalmological Society; aged 91; died, September 23.

**Frank George Ungerman** • McKeesport, Pa.; University of Louisville (Ky.) Medical Department, 1912; aged 50; on the staff of the McKeesport Hospital, where he died, September 26, of cerebral hemorrhage and chronic nephritis.

**John W. Bachelor**, Oxford, Mich.; Detroit College of Medicine, 1897; member of the Michigan State Medical Society; served during the World War; aged 63; died, September 23, of carcinoma of the stomach with metastasis.

**John Warren Germany**, Ennis, Texas; Kentucky School of Medicine, Louisville, 1890; served during the World War; formerly on the staff of the Municipal Hospital; aged 71; died, September 23, of coronary thrombosis.

**Joseph Welch Scott**, West Point, Miss.; Medical Department of Tulane University of Louisiana, New Orleans, 1887; member of the State Medical Association of Texas; aged 74; died, September 11, at the Ivy Hospital.

**Robert Burtis Blanchard** • Jamestown, N. Y.; University of Buffalo School of Medicine, 1906; aged 55; on the staff of the

Jamestown General Hospital and the Woman's Christian Association Hospital, where he died, September 15.

**Frank Mansfield Sharpe**, Oconomowoc, Wis.; College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1887; aged 75; died, September 13, of chronic myocarditis and arteriosclerosis.

**Samuel Beecher Pray** ♂ New Rochelle, N. Y.; University and Bellevue Hospital Medical College, New York, 1901; on the staff of the New Rochelle Hospital; aged 65; died, September 7, in the Glens Falls (N. Y.) Hospital.

**William Walter Pretts** ♂ Milwaukee; Northwestern University Medical School, Chicago, 1900; served during the World War; on the staff of the Veterans Administration Facility; aged 65; died, September 7, of heart disease.

**Alfred Elias Orr**, Montreal, Que., Canada; McGill University Faculty of Medicine, Montreal, 1888; at one time lecturer in anatomy and demonstrator of biology at his alma mater; aged 77; died, September 23.

**John Bernhard Thompson**, Wittenberg, Wis.; Milwaukee Medical College, 1912; served during the World War; aged 51; died, September 6, in the Memorial Hospital, Antigo, of peritonitis and ruptured gallbladder.

**Arthur Franklin Gerberich**, Limeport, Pa.; Medical-Chirurgical College of Philadelphia, 1909; member of the Medical Society of the State of Pennsylvania; aged 52; died, September 21, of pulmonary carcinoma.

**Aloys Heinen**, Chicago; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1904; aged 76; died in September in Germany of chronic myocarditis and arteriosclerosis.

**James W. Ludden**, Cincinnati; University of the South Medical Department, Sewanee, Tenn., 1894; aged 75; died, September 28, in St. Agnes Hospital, Philadelphia, of hypostatic pneumonia and arteriosclerosis.

**Thomas Richmond**, Guthriesville, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1881; member of the Medical Society of the State of Pennsylvania; aged 81; died, September 2, of uremia.

**Peter Lorentz Vistauet**, Thief River Falls, Minn.; University of Minnesota College of Medicine and Surgery, Minneapolis, 1902; aged 67; died, September 22, of bronchopneumonia and myocardial insufficiency.

**Jacob B. Oliver**, Brazil, Ind. (licensed in Indiana in 1897); formerly a medical missionary and minister; aged 91; died, September 21, of carcinoma of the right cheek and jaw and bronchopneumonia.

**Philip Arlis Hilton**, Waynesboro, Va.; Howard University College of Medicine, Washington, D. C., 1920; aged 49; died, September 25, in the University Hospital, Charlottesville, of bronchopneumonia.

**Willard Hanks Gage**, Seattle; Eclectic Medical Institute, Cincinnati, 1899; aged 60; died, September 16, of injuries received in an automobile accident in the mountains near Jackson, N. Y.

**Harry Melville Dougherty** ♂ Pittsburgh; University of Pittsburgh School of Medicine, 1925; served during the World War; aged 41; died, September 13, of pulmonary tuberculosis.

**John Walton Shultz**, Kansas City, Mo.; University Medical College of Kansas City, Mo., 1902; aged 79; died, September 16, of chronic myocarditis, cystitis and arteriosclerotic nephritis.

**John Peyton Foster**, La Crosse, Mo.; Marion-Sims College of Medicine, St. Louis, 1893; aged 74; died, September 29, of acute dilatation of the heart, arteriosclerosis and nephritis.

**J. M. Caldwell**, Augusta, Ga.; Medical College of Georgia, Augusta, 1897; at one time demonstrator and instructor of obstetrics at his alma mater; aged 68; died, September 16.

**Adolph F. Wohlenberg**, Kooskia, Idaho; College of Physicians and Surgeons of Chicago, 1894; formerly a druggist; aged 76; died, September 23, of carcinoma of the prostate.

**Alexander Joseph Slaven**, Columbus, Ohio; Bellevue Hospital Medical College, New York, 1898; aged 67; died, September 19, of cerebral embolism and arteriosclerosis.

**Charles Terbush Haines**, Utica, N. Y.; Pulte Medical College, Cincinnati, 1887; on the staff of the Utica Memorial Hospital; aged 75; died, September 30, of heart disease.

**Robert C. Wear**, Baxter Springs, Kan.; University of Kansas City Medical Department, 1885; member of the Kansas Medical Society; aged 80; died, September 9.

**Lawrence Arthur Petty**, Charleston, W. Va.; University of Cincinnati College of Medicine, 1913; served during the World War; aged 52; died, September 14.

**Benjamin Frank Hutchings**, Crawfordsville, Ind.; Medical College of Ohio, Cincinnati, 1872; aged 92; died, September 29, of chronic nephritis and arteriosclerosis.

**Bruce Jonas Crisman**, Utica, N. Y.; Syracuse University College of Medicine, 1907; aged 56; died, September 29, in St. Luke's Hospital of heart disease.

**Rufus V. Gamble**, Elyria, Ohio; Western Reserve University Medical Department, Cleveland, 1871; aged 90; died, September 28, of intestinal obstruction.

**George Washington Henderson**, Westerville, Ohio; Starling Medical College, Columbus, 1892; aged 81; died, September 23, of cerebral hemorrhage.

**Johnston Frank**, Dallas, Texas; Medical College of Ohio, Cincinnati, 1880; Jefferson Medical College of Philadelphia, 1886; aged 81; died, September 29.

**Clarence Woodson Warnock**, Huntington, W. Va.; Kentucky School of Medicine, Louisville, 1907; aged 57; died, September 16, in St. Mary's Hospital.

**Mary Elizabeth Fetzer Mazza**, East Cleveland, Ohio; Western Reserve University School of Medicine, Cleveland, 1928; aged 36; died, September 14.

**Samuel Cooke Ingraham**, Philadelphia; Jefferson Medical College of Philadelphia, 1886; aged 88; died, September 11, of cystitis, prostatitis and uremia.

**Francis Boyd Carleton**, Boston; Boston University School of Medicine, 1894; aged 73; died, September 7, at his summer home in Sebago Lake, Maine.

**John C. Swatzlander**, Fontana, Calif.; University Medical College of Kansas City, Mo., 1897; aged 66; died, September 11, of cirrhosis of the liver.

**Napoleon B. Winfrey**, Kansas City, Mo.; Kansas City Medical College, 1881; aged 86; died, September 10, of chronic myocarditis and nephritis.

**C. E. Smith**, Enid, Okla.; Louisville (Ky.) Medical College, 1893; aged 72; died, September 10, in a local hospital of prostatitis and urinary calculi.

**Walter Kenney Barrett**, Milford, Del.; University of Pennsylvania Department of Medicine, Philadelphia, 1895; aged 68; died, September 10.

**Ward Greene Clarke**, Chicago; Rush Medical College, Chicago, 1882; aged 79; died, October 27, of coronary and cerebral thrombosis.

**Sara May Donnell Wolverton**, Merchantville, N. J.; Woman's Medical College of Pennsylvania, Philadelphia, 1904; died, September 27.

**John Francis Heffernan** ♂ Albany, N. Y.; Albany Medical College, 1901; on the staff of St. Peter's Hospital; aged 61; died, September 8.

**Walter Davis Wilson**, Schlater, Miss.; University of Tennessee Medical Department, Nashville, 1893; aged 71; died, September 23.

**Henry Franklin Bean**, Portsmouth, Ohio; University of Louisville (Ky.) Medical Department, 1876; aged 85; died, September 11.

**Charles Garfield Chapin**, Brantford, Ont., Canada; University of Toronto Faculty of Medicine, 1906; aged 54; died, September 26.

**Joseph Napoleon Bonaparte Rawle**, Brooklyn; Eclectic Medical College of the City of New York, 1899; aged 72; died, September 30.

**Andrew J. Allen**, Subiaco, Ark.; Gate City Medical College, Dallas, Texas, 1907; aged 70; died, September 20, of pulmonary tuberculosis.

**William Lynn Wilson**, St. Joseph, Mich.; Detroit College of Medicine, 1890; aged 71; died, September 6, of carcinoma of the prostate.

**Adam Hume Millar**, Toronto, Ont., Canada; University of Toronto Faculty of Medicine, 1908; aged 58; died, September 28.

**Daniel Paul Odom**, Lyons, Ga.; Georgia College of Eclectic Medicine and Surgery, Atlanta, 1901; aged 68; died, September 25.

**Samuel McLean Withers**, Moultrie, Ga.; North Carolina Medical College, Davidson, 1902; aged 61; died, September 4.

**Hugh C. Cunningham**, Roganville, Texas; Jefferson Medical College of Philadelphia, 1885; aged 76; died in September.

**William A. Reed**, New York; Hahnemann Medical College and Hospital, Chicago, 1880; aged 83; died, September 15.

**Waldemar Ude**, St. Louis; Marion-Sims College of Medicine, St. Louis, 1892; aged 67; died, September 17.

## Bureau of Investigation

### TUCKER'S SPECIFIC FOR ASTHMA CRIES HELP!

#### New Legislation Causes Pain and Anguish to Proprietors of an Old, Old Asthma Specific

As long ago as May 20, 1911, the Bureau of Investigation (then known as the Propaganda Department of the American Medical Association) first called attention to the nostrum "Dr. Nathan Tucker's Specific for Asthma, Hay Fever and Nasal Catarrh." In a Notice of Judgment issued Sept. 29, 1911, the government declared the "specific" misbranded on two counts. Thirteen years later THE JOURNAL (Nov. 1, 1924) pointed out editorially that the Commissioner of Internal Revenue had replied to an inquiry from THE JOURNAL that, while "Tucker's Asthma Specific" carried a label admitting the presence of 5 grains of cocaine to the fluidounce, before the remedy reached the public the cocaine became hydrolyzed and there was either no cocaine or but an infinitesimal quantity. The commissioner also expressed the opinion that the mail-order distribution of this nostrum served "a great humanitarian cause"; therefore it had been decided by the Treasury Department to take no action enjoining its distribution. THE JOURNAL concluded its comments, in part, as follows:

"If it contains cocaine or a derivative of cocaine, and the Treasury Department has admitted that it does, then its sale violates the Harrison Narcotic Law, for that law applies just as much to the derivatives of cocaine as it does to cocaine itself."

The present promoters of the product appear to be Drs. W. B. and G. B. Robinson, and they are apparently concerned over the effect of the new Food, Drug and Cosmetic Act on their product. According to the Mount Gilead (Ohio) *Sentinel* for Sept. 8, 1938, Dr. W. B. Robinson addressed the local Kiwanis Club in part as follows:

"There are now patients using this remedy in every town of 500 or more population in the entire country, and this has resulted solely from one person securing relief and then telling others."

"Legislation has been recently passed at Washington which will force every such patient to come to Mount Gilead for treatment. [It would indeed be a sight worth seeing if citizens from every town of the United States of more than 500 population were to gather together into a Coxey's army and march on to Mount Gilead.—Ed.] Only a small percentage of such cases can afford to come to Mount Gilead, and as a result of this hasty and ill considered legislation thousands of asthma sufferers will be unable to secure relief."

"Unless an amendment is made to the law, thousands of asthma sufferers who now obtain relief from the use of this remedy will be doomed to suffer indefinitely, many of them all the remainder of their lives, because of their inability to come to Mount Gilead from their homes hundreds of miles away."

This colossal assertion by Dr. Robinson presumes that these sufferers could not obtain more scientific and efficacious treatment by inquiring of their family doctor, or an allergist in their locality, than they obtain at the present time from Mount Gilead.

The Drs. Robinson are so concerned about this matter that a form letter addressed "To Our Patients" is apparently being distributed at the present time. The letter says in part:

"The new law quite properly exempts physicians from its requirements, but into the final draft some influence slipped twenty-one words which provide that diagnosis may be made only after a personal examination."

The letter even goes so far as to admit that, "in treating most of the ills that flesh is heir to, a personal examination is essential [It adds, however] but 48 years of experience, and the statements in our text books have convinced us that this is an unnecessary and an unreasonable requirement when dealing with such characteristic syndromes as Asthma and Hay Fever."

It might be suggested that the Robinsons consult some more recent textbooks for details of skin tests, elimination diets and other means of determining the causative agents in asthmatic conditions. As a result of such tests, causative agents can be frequently eliminated and desensitization to such agents sometimes accomplished. But, of course, this constitutes scientific treatment.

The Drs. Robinson say that they are "delighted to see the continuing procession of patients that come to our office, but

experience has doubtless proven that we can relieve your Asthma or Hay Fever without the necessity of a personal examination." Why the "doubtless"?

The concluding paragraph of the form letter is especially interesting. It reads:

"At the next session of Congress we are going to ask for an amendment that will enable us to serve you as we have in the past. If you with our tens and tens of thousands of other patients will bring this to the attention of your Senators and Representative, either by a letter or a personal interview, we are sure our amendment will be accepted. We would appreciate copies of any letters, or report of your personal interview."

A parallel to this form letter was forwarded by Dr. W. B. Robinson "To Our Patients In New York" under date of Feb. 18, 1913. It read as follows:

"The Walker Bill No. 692 has been submitted to the Legislature of New York State. If this Bill becomes a law we cannot send you further fluid."

"If your physician should be fortunate enough to know a prescription that would relieve your asthma he could come to your bedside and give it to you. If, however, it contained cocaine you would render yourself liable to fine and imprisonment if you kept his medicine in your house over ten days; in other words, it would be unlawful for you to have in your possession over ten days any medicine which contained cocaine in any form or in any dosage. This means that if it happened to be eleven days after you received the prescription before you had an attack of asthma, you could not legally use it."

"The purpose of this law is to prevent the indiscriminate sale of cocaine to the drug fiends or in any way that might make drug users. In so far as it accomplishes this it is good. The workings of it, however, we are sure would be a very great hardship to you."

"We trust you will take this up with your Senators and Representatives, or with any prominent people you know in your State; give them your opinion of our Treatment; state to them frankly whether it has relieved you and if it has in any way produced a drug habit."

"If you know any of the Senators or Representatives personally, I would be pleased if you would give me a letter of introduction to them. "PLEASE ACT IMMEDIATELY."

It is interesting to note the more recent attempt on the part of this nostrum manufacturer to counteract the useful and effective measures which are part of the new Food, Drug and Cosmetic Act. The provisions which make up the new Food, Drug and Cosmetic Act are designed in part to prevent the mulcting of innocent people who believe that they can be treated by "long distance" for conditions which require personal medical attention.

### KELPEP, PROSTAX AND GLANMEND

#### The Frauds of Lord & Company Are Debarred from the Mails

One Mrs. Rose Lord Pressner of Ridgewood, Brooklyn, N. Y., doing business under the trade styles "R. Lord," "Lord & Co." and "Lord's," sold mail-order nostrums for the alleged cure of lost sexual vitality and allied conditions. From the evidence it appears that Mrs. Pressner contacted her victims through advertisements carried in newspapers which are not particular about the type of advertising they accept. She also, it is stated, purchased "sucker lists" from concerns that deal in such merchandise.

In her advertising Mrs. Pressner stated that she had "seen a lot of men worn down Physically and Mentally." She suggested that those who lacked the "power of erection" should take her "Kelpep," which, she claimed, was "number one in building up" and "one single teaspoonful [of which] contains more natural iodine than 427 pounds of spinach" and was "proportionately 700 times richer than oysters." She also recommended her "Glanmend," which she called "the newer tonic tablet treatment" that would "put brand new pep into your tired body almost like magic."

Mrs. Pressner was also solicitous of those who had symptoms of prostate "trouble." She declared that "a man is as old as his prostate." For these she had some rectal suppositories called "Prostax." In addition, as a sideline she added to her armamentarium for those males who lacked vim, vigor and vitality a device that she called "Giant Developer." This was actually a mechanical masturbator of a type that the Post Office has time and again debarred from the mails.

When Lord & Co., et al., were called on last April to show cause why a fraud order should not be issued against them, no person appeared at the hearing but a firm of attorneys forwarded a written answer and certain exhibits. The postal officials

declared that there were no physicians, chemists or pharmacists connected with the business but that Mrs. Pressner was the sole owner and the only person involved in the operation of the business.

Government chemists reported that Kelpep tablets consisted essentially of seaweed with a fraction over one one-hundredth of a grain of iodine to each tablet. The Glanmend "tonic" was found to contain some animal tissue with strychnine and saw palmetto. The strychnine was the only ingredient with a known pharmacologic effect, and the claim that Glanmend would restore sexual vitality was declared fraudulent. The suppositories which were supposed to cure "prostate trouble" were found to have a base of cocoa butter in which were incorporated about 3 per cent ichthammol and small amounts of atropine, hydrastine and oil of juniper. The claim that this would reduce the size of a hypertrophied prostate or eliminate all symptoms of prostate trouble was declared false.

Mrs. Pressner's scheme was declared to be one for obtaining money through the mails by means of false and fraudulent pretenses, representations and promises. The mails were closed to R. Lord, Lord & Co. and Lord's on July 1, 1938.

## Correspondence

### RACIAL DIFFERENCES IN HYPERTENSIVE DISEASE

To the Editor:—In THE JOURNAL October 29, page 1684, a reply to a query asking about the racial incidence of hypertension stated that there is no well defined racial difference in the incidence of hypertensive disease. This statement is not at all in agreement with the literature, especially that which has to do with hypertension in colored people.

The proneness of Negroes to hypertension and its resultant or concomitant cardiac and renal changes has been noted and studied by several investigators. Adams (*Am. J. M. Sc.* 184:342 [Sept.] 1932) made several blood pressure readings on each of 5,074 male employees and one reading on each of 9,000 applicants for employment. About one third of these were colored and the remainder white. The average white systolic pressure was 121 mm. and the diastolic 81 mm.; for the colored, systolic 128 mm., diastolic 85 mm. In each age group the Negro systolic pressures were from 4 to 13 mm. higher than those of the white men, and the diastolic pressures were from 2 to 6 mm. higher. Beyond 40 years of age the pressures of the Negroes advanced more rapidly than of the white men. The maximum differences of the average systolic pressures in the age groups occurred at ages 46-50 years and at 56-60 years, when the colored systolic pressures were respectively 11 mm. and 13 mm. higher. The maximum difference in diastolic pressure was in the 41-45 year and 56-60 year groups, which in both instances amounted to 6 mm. over the white. The average of the maximum systolic pressures of all 5 year age groups from 18 to 65 was 205 mm. for the white men and 222 mm. for the Negroes. The average of the minimum systolic pressures was 79 mm. for both races. Damage to the aortic valve in hypertension, as evidenced by an increased pulse pressure, occurs earlier and more frequently in Negroes. Jaffé (*Zentralbl. f. allg. Path. u. path. Anat.* 55:209, 1922) found, in his necropsy experience at the Cook County Hospital in Chicago, that hypertension and malignant nephrosclerosis were much more prevalent in Negroes and that also the average age at death was lower. Moritz and Oldt (*Am. J. Path.* 13:679 [Sept.] 1937) made a detailed study of arteriolar sclerosis in a necropsy population of 1,177 individuals. Negroes made up 20 per cent of this population but furnished 30 per cent of the cases of chronic hypertension, indicating again that the disease has a higher incidence among them than among the white men. Analysis of the ages in the hypertensive cases showed that the mean age

of the Negroes was eight years lower than that of the white men. These patients with hypertension died of uremia, cardiac failure or cerebral hemorrhage, but about the same percentage of Negroes and white men died of each of these causes. Histologic studies of each type, distribution and severity of arteriolar changes in white and colored nonhypertensive and hypertensive men showed no racial differences.

Schulze and Schwab (*Am. Heart J.* 11:66 [Jan.] 1936) applied the various theories that have been applied to explain hypertension to account for the difference between white persons and Negroes. They disclaim the role of inheritance, since hypertension is absent in native Africans and there is not enough intermixture with white persons to account for the departure from this African characteristic. Moreover, they say, the mendelian law of inheritance is not in accord with the excess of hypertension in Negroes over white persons, which amounts to 2.5 times. The effect of the change from African to American climate is considered but, although Europeans and Americans show a lowering of blood pressure in the tropics, there is no evidence that the contrary circumstances produce opposite results. Although syphilis is present in Negroes, its role in hypertension is questionable. (The relation of syphilis to hypertension is discussed by Horine and Weiss: *Am. Heart J.* 6:121 [Oct.] 1930.) Likewise diet and obesity are unsuitable as explanations of hypertension. Schulze and Schwab resort to the theory of nervous factors to account for the high rate of hypertension in Negroes. They believe that the true explanation is the stress and strain incident to adjustment to a new civilization.

Statistics show that arteriosclerosis causes relatively more heart disease and hypertension causes relatively less heart disease in white persons than in Negroes. Stone and Vanzant (*THE JOURNAL*, Oct. 29, 1927, p. 1473) found that 50.5 per cent of the heart disease in Negroes was caused by hypertension as compared to 45.3 per cent in white persons. Arteriosclerosis produced 19.8 per cent of the cases in white persons and 6.3 per cent in Negroes. In the same clinic a few years later Schwab and Schulze found that 42.4 per cent of the cases in white persons and 63.2 per cent of the cases in Negroes were due to hypertension and 35.9 per cent of the cases in white persons and 13.7 per cent of the cases in Negroes were produced by arteriosclerosis. Arteriosclerosis is a disease primarily of advanced age, and the lower rate of this condition in Negroes might mean a lower proportion of the upper age groups in this race.

Hedley (*Pub. Health Rep.* 50:1127 [Aug. 23] 1935) points out that Negroes dying in the arteriosclerotic-hypertensive group of heart disease do so at an earlier age than white persons. In his series the average age of Negroes at death was 54.6 years and the average age of white persons was 66.6 years. The peak of deaths of Negroes was at 40-49 years and of white persons it was 60-69 years. In the white persons 40.4 per cent of these deaths occurred at the age of 70 years or more but only 16.7 per cent occurred at this time among the Negroes. Death occurred before 40 years in 0.6 per cent of the white persons and in 12.9 per cent of the Negroes.

Jaffé was of the opinion that the large amount of hypertension in Chicago Negroes was due to their recent immigration from the South.

Polak (*Am. J. Obst. & Gynec.* 4:227 [Sept.] 1922) says that fibroids, which are very prevalent in Negro women, have no effect on blood pressure, although a relation between these two conditions has been suggested.

Schwab (*Proc. Soc. Exper. Biol. & Med.* 32:583 [Jan.] 1935) determined the results of the vasomotor test of Hines and Brown (*Ann. Int. Med.* 7:209 [Aug.] 1933) on 172 white persons and 153 Negroes between the ages of 15 and 35 years. In this test the hand and wrist were put in cold water (from 4 to 5 C., or 39 to 41 F.) and while in the bath blood pressure readings

were taken thirty, ninety and 150 seconds after immersion. He found that the elevation of blood pressure is more marked in Negroes and concluded that there is a quantitative racial difference in reaction to a standard vasomotor stimulus, indicating a more sensitive vasomotor mechanism in the Negro. This evidence is used in support of the neurogenic theory of hypertension.

JULIAN H. LEWIS, M.D.,  
Department of Pathology and the  
Otto S. A. Sprague Memorial Institute,  
University of Chicago.

## Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

### AIR CONDITIONING FOR PNEUMONIA

*To the Editor:*—What is the latest method of treating both lobar and bronchial pneumonia in an air conditioned room in a hospital? What are the advantages? What are the contraindications?

ALBERT C. LUNDGREN, M.D., Minneapolis.

**ANSWER.**—Whenever a patient is placed in an oxygen tent, the atmosphere surrounding him is conditioned. When tents are well designed and operated, the atmospheric conditions assist cooling and maintain a desired partial pressure of oxygen and of carbon dioxide.

The essential factors in proper atmosphere conditioning have been analyzed and desirable conditions formulated (Bullowa, J. G. M.: *Management of the Pneumonias*, New York, Oxford University Press, 1937). The factors controlled are temperature, relative humidity, rate of air movement, oxygen concentration, carbon dioxide concentration and removal of noxious substances, either chemical or particulate, which cause odors.

The necessary loss of oxygen and the introduction of surrounding unconditioned atmosphere when services are rendered to the patient are inherent disadvantages in even well designed and operated individual oxygen enclosures or tents. Some patients have a feeling of confinement and isolation. Either the nursing and examinations are neglected in order to retain the high and uniform oxygen concentration or desirable and even essential atmospheric conditions are sacrificed.

In some climates and under some atmospheric conditions and, in the case of less severely stricken patients, uniform high oxygen concentration may be sacrificed in order that better nursing care may be provided and physical examinations performed. Nevertheless, in some late and prostrated patients disaster may follow when, for even brief periods, oxygen concentration is diminished to provide nursing care and careful physical scrutiny.

To overcome these disadvantages, oxygen rooms have been provided in some well equipped hospitals. In them patient and nurse are simultaneously enclosed. Both nursing care and the physician's observations may be provided without loss of optimal atmospheric conditions.

Conditions desirable for febrile anoxic patients may not be agreeable to those entering a well conditioned room from warm or humid surroundings. This may lead to unwise criticism. Recording instruments are accordingly desirable to proper operation of atmosphere control rooms.

Excellent, satisfactory air conditioned rooms are in use at the Rockefeller Institute, the Presbyterian and the Harlem hospitals in New York. Those responsible for the care of patients with lobar and bronchopneumonia in these hospitals believe that they are of great value and do not wish to give them up. In various centers improperly designed chambers have been built without suitable locks, adequate provision for air conditioning or economical maintenance of the oxygen concentration. Naturally, these have proved unsatisfactory and have been abandoned. The principle of air conditioning in the treatment of pneumonias is sound and in practice desirable and may be economical.

The cost of maintaining a well designed, maintained and operated oxygen chamber is not considerably greater than the cost of maintaining an oxygen tent. The first cost of installation is offset in the case of patients desperately ill by the much more satisfactory results.

### ESOPHAGOBRONCHIAL FISTULA

*To the Editor:*—A man aged 32 has had an esophageal-bronchial fistula for several years following a traction diverticulum. There is no evidence of tuberculosis. He has no fever. The blood sedimentation (Westergreen) is 30, the leukocytes number 10,100, and the hemoglobin (Sahli) is 100 per cent. He has had several attacks of bronchial pneumonia and complaints of violent coughing. X-ray examination shows esophageal-bronchial fistula of a large size and signs of gastritis and cardiospasm. He has been nourished through a duodenal sound with relief. He weighs 79 Kg. What treatment can be followed? Is there any chance of operating without opening the thorax?

L. ZWILLINGER, M.D., Prostějov, Czechoslovakia.

**ANSWER.**—Nonmalignant esophagobronchial fistulas are rarely observed. Ribbert has suggested a developmental origin, but it is generally agreed that they are usually secondary to traction diverticula caused by the healing of tuberculous lymph glands. Foreign bodies may occasionally be the cause. Death from pulmonary suppuration is almost certain to ensue unless the fistula is closed. It is surprising that the defect can be tolerated over a period of years, but a chronic course is not uncommon.

The condition is so rare that no one has had extensive experience in the treatment. In one case Clerf succeeded in closing the fistula by cauterizing its surfaces with silver nitrate through the esophagoscope. For several weeks subsequent to the procedure, feeding was done through a catheter passed into the stomach. In the case under consideration there are two factors which make it peculiar. These are the cardiospasm and what seems to be a large pulmonary cavity. The obstruction at the lower end of the esophagus and the dilatation of the esophagus must be important in favoring the patency of the fistula and the passage of food through it. Probably the first step in treatment should be to relieve the cardiac obstruction. The second should be an attempt to close the fistula by cauterization with silver nitrate. If these procedures are successful the pulmonary suppuration has still to be dealt with. Once the fistula is closed, this may improve sufficiently not to require treatment. Drainage of an abscess or lobectomy for bronchiectasis may be necessary.

The reproduction of the roentgenogram leaves uncertainty as to whether what seems to be a cavity in the lung is truly such a cavity or is barium in the fundus of the stomach which has been displaced upward by an elevated diaphragm.

If the cauterization fails to close the fistula, surgical closure must be attempted. The almost certain presence of extensive pleural adhesions makes the question whether the procedure could be performed extrapleurally or intrapleurally unimportant. Two surgical approaches can be conceived of: direct extrapleural exposure of the diverticulum without mobilization of the lung and mobilization of the lower lobe with coincidental exposure of the tract and lobectomy. In the first procedure two ribs directly posterior to the lesion should be resected through a paravertebral incision and the posterior mediastinum reached by dissecting the parietal pleura from the ribs and vertebral bodies. In the second procedure a long posterior segment of the eighth rib should be resected, the pleural cavity opened widely, the lung freed well to the hilus, the diverticulum located and closed, and a lobectomy performed. In either operation one would anticipate considerable difficulty in locating the diverticulum. A catheter inserted into the fistula through the esophagoscope shortly before the operation should help in localization.

### COLLES' FRACTURE AND TYPHOID

*To the Editor:*—A boy 14 years old was admitted to the hospital with Colles' fracture, which was sustained two weeks before. No treatment was administered for the fracture. The day after coming to the hospital he had a temperature of 101.4 F. Several days later a diagnosis of typhoid was made. What is your opinion as to the proper procedure? Should the fracture be reduced immediately or would it be advisable to wait until the typhoid subsides? What are the complications that may develop in such a case if the fracture is reduced?

MORTON J. EARLEY, M.D., Spangler, Pa.

**ANSWER.**—Healing of a Colles fracture in a 14 year old boy is so rapid that at the end of two weeks it is unlikely that much could be done in the way of a reduction without an open operation. If the deformity is not bad, readjustment will take place in a child of this age, giving a surprisingly good result without reduction. While typhoid patients stand a general anesthetic reasonably well, the general condition of the patient must be taken into consideration before undertaking even a closed reduction. Typhoid is a general blood infection and is occasionally followed by osteomyelitis. An open operation would be likely to be followed by infection and therefore should not be considered at the present time. The probabilities are that it would be much safer to leave the fracture entirely alone.

## NO DRUG TO INCREASE LYMPHOCYTES

*To the Editor.*—What drugs, if any, stimulate the lymphatic system so as to increase the number of lymphocytes in the blood stream? I have been unable to find any literature on the subject. Is there any drug that will stimulate the lymphocytes, as pentnucleotide does the polymorphonuclear cells?

I. L. CUTLER, M.D., Rutland, Mass.

**ANSWER.**—As far as is known there are no drugs that specifically stimulate the lymphatic system or the production of lymphocytes. Certain diseases, such as pertussis and infectious mononucleosis, are accompanied by a lymphocytosis, but the cause for this is not known.

## RELAPSING FEVER OR TULAREMIA

*To the Editor.*—A man aged 80 was visiting in the Teton Mountains in Wyoming in the early part of July. A few hours after carrying an armful of wood into the house he noticed on each arm what he thought were ticks. He went to the doctor in the community, who diagnosed his condition as "tick fever." The symptoms were fever, nausea, vomiting, numbness in both arms, elbows and wrists, numbness of the right leg and pain in the back of the neck and in the back. The temperature rose to 103 F. He came home and since that time soreness in the muscles and loss of appetite have persisted. There is elevation of temperature daily to 101 F. My diagnosis is relapsing fever. Could you supply me with the latest treatment of this condition?

M.D., Illinois.

**ANSWER.**—The symptoms presented by this patient are insufficient for a diagnosis of relapsing fever. In this disease there is an incubation period of from six to nine days between the infected tick bite and the onset of symptoms. The febrile stage lasts three days, followed by an afebrile period of four or five days.

Not all tick bites cause relapsing fever. Numerous persons in the region of Gold Park, Nev., have been bitten by ticks with no untoward consequences. Because of the daily elevation of temperature, tularemia should also be considered.

Diagnosis of relapsing fever rests on finding the spirochetes in a blood smear taken during the febrile stage. Smears should be stained with 20 per cent Giemsa stain for thirty minutes.

For treatment, neosphenamine is specific when given in sufficient doses during the period of rising temperature. The same dose as in antisyphilitic therapy is indicated. If inadequate amounts of the drug are used, relapses are more prone to recur.

## HUNTINGTON'S CHOREA

*To the Editor.*—What is the latest treatment for Huntington's chorea? Please list the literature supplementing this information.

MORTON M. STERN, Medical Student, Newark, N. J.

**ANSWER.**—A search of the literature published in the last five years does not reveal any articles dealing with the treatment of Huntington's chorea nor are there any suggestions as to treatment to be found in the discussion of this condition in the articles found in the late systems of medicine. This question was further taken up with several prominent neurologists and no knowledge of any new treatment was reported.

## PULMONARY TUBERCULOSIS IN LABORATORY WORKER

*To the Editor.*—A man aged 30 is now under treatment for pulmonary tuberculosis. Laboratory reports are positive; physical and x-ray examinations indicate a moderately advanced process with two small cavities in the apex of the right lung. The remainder of the lung appears clear. An exhaustive search of the family history and any possible outside contacts reveals nothing which would indicate a possible source of infection. The patient has worked for the last six years in a diagnostic laboratory doing a moderate number of positive sputum examinations. X-ray examinations of the chest four years ago revealed no evidence of pulmonary tuberculosis. Does pulmonary tuberculosis occur in laboratory technicians as a direct result of their work in a diagnostic laboratory making a moderate number of positive sputum examinations? If so, what is the percentage? What is the likelihood of a man aged 30, in apparent good physical health and having a negative chest roentgenogram, developing pulmonary tuberculosis as the result of his six years' work in a diagnostic laboratory? Could this case be termed an occupational disease under the workmen's compensation act?

EDWARD D. DAKE, M.D., Rome, N. Y.

**ANSWER.**—Since the patient is 30 years old and the x-ray examination of the chest four years ago revealed no evidence of pulmonary tuberculosis, one should also know whether he reacted to tuberculin at that time. A laboratory worker who makes examinations of sputum containing tubercle bacilli may easily contract an infection provided extreme care is not exercised. In the occasional case there is good evidence of the disease having been contracted in the laboratory; that is, non-reactors have become reactors while at work with no other known contact with tubercle bacilli and have later developed the disease clinically. Even then it is difficult to be certain that the infection was not contracted outside the laboratory. As

there are few places where large numbers of laboratory workers are employed, it is difficult to obtain sufficiently large figures to determine accurately what percentage fall ill from tuberculosis. In this case, if no tuberculin test was administered four years ago it would be impossible now to determine when the infection first developed; it may have been many years before the patient was employed in the diagnostic laboratory and the present manifestations could easily be the result of endogenous reinfection.

X-ray examinations of tuberculin reactors are of but little help in detecting the primary tuberculosis complex, since rarely does the roentgenogram reveal such complexes in more than 10 or 15 per cent of the reactors examined. Therefore, unless more evidence is available than negative x-ray observations four years ago, it would be a difficult matter to prove that this man's tuberculosis was contracted in the laboratory so as to be termed an occupational disease under the workmen's compensation act, unless the act in the state in which he resides specifically provides for the development of clinical disease while at work and does not take into consideration the possible earlier origin.

## GASTROINTESTINAL UPSETS AND CHLORINE IN DRINKING WATER

*To the Editor.*—Is it true that for many persons the drinking of chlorinated water leads to stomach and intestinal complaints? Is it true that in many localities people do not fully appreciate that this is the cause of repeated attacks of mild cramps, colic, belching and a host of indefinite gastrointestinal symptoms?

M.D., Minnesota.

**ANSWER.**—The accepted concentration of chlorine in the purification of water is one part in a million. Chlorine gas reacts with organic material and with water to form unstable hypochlorous acid. It is difficult to understand how such a low concentration of chlorine or chlorine compounds could cause digestive disturbances.

Whipple (*Microscopy of Drinking Water*, ed. 4, New York, John Wiley & Sons, 1927) states that:

The chlorination of waters which contain certain organic compounds in solution will cause tastes and odors of different characteristics and degrees of intensity depending upon the nature of the organic matter and its concentration. By-products, tastes and odors should be subdivided into:

A. Those caused by combination of chlorine and algae oils or other vegetable or animal matters.

B. Those resulting from chlorine and specific chemicals such as phenols and cresols.

An overdose of chlorine will mask the chlorophenol taste, but upon heating or otherwise driving off the "free" chlorine, the by-product taste still remains. The product is apparently of low volatility and stable, since boiling away 50 per cent of the sample fails to rid the water of the disagreeable taste.

It is perhaps possible that gastrointestinal upsets, such as flatulence, "sour stomach," constipation or diarrhea, might be due to chemical alterations, but it is much more likely that the chlorination has nothing to do with the disturbances. Many of these are of bacterial origin but are transmitted by way of infected food or by food handlers rather than by water. Another possibility is that inadequate chlorination may permit infections to be transmitted by way of the drinking water. The taste of chlorine leads to the false incrimination of the chlorine as the cause of the disturbance. Boiling the water drives off the "free" chlorine and also kills the bacteria.

## IRON INTRAVENOUSLY FOR ANEMIA

*To the Editor.*—I have been interested in the use of iron preparations administered intravenously in the treatment of hypochromic anemias. Could you give me some information as to their use and their reactions and whether they have or have not been considered by the Council on Pharmacy and Chemistry?

MURRAY W. SHULMAN, M.D., Newark, N. J.

**ANSWER.**—The intravenous or intramuscular administration of iron in hypochromic anemia is to be condemned in all but extraordinary circumstances. If given in adequate amounts to cure the anemia, it is painful, toxic, dangerous and expensive. Heath and Patek (*Medicine* 16:267 [Sept.] 1937) state that they have never seen a case that responded to parenteral iron which failed to respond equally well to adequate dosage by mouth. (Failure to obtain results with iron by mouth is usually due to inadequate dosage.) Only in cases in which severe diarrhea or some other serious contraindication to oral therapy exists should parenteral treatment be considered. While the Council has accepted one iron preparation for injection (green iron and ammonium citrate, U. S. P.), it is stated in connection with the Actions and Uses as given in New and Nonofficial Remedies that "the Council is not convinced that the intra-

muscular or hypodermic administration of iron yields effects which differ from those obtained by the oral administration; however, the unsettled state of iron therapy and the rather large clinical use of iron by intramuscular or subcutaneous injection appears to justify the provisional acceptance of this preparation."

#### CHILLS AND FEVER AFTER STRENUOUS PHYSICAL TRAINING

To the Editor:—A man aged 24, weighing 150 pounds (68 Kg.) and 5 feet 10 inches (178 cm.) in height, had been training extensively for two months prior to a track meet, running between 2 and 3 miles plus calisthenics daily, working at the same time from 5 p. m. to 1 a. m. The days before the meet he had fever, chills and a clammy cold sweat over his body lasting for several minutes. July 3, the next day, physical examination was negative, but the development of an afternoon temperature from 101 to 103 F. daily kept him in bed. The hemoglobin was 90 per cent, red cells 5,400,000, white cells 8,000, polymorphonuclear leukocytes 74 per cent, lymphocytes 24 per cent, monocytes 2 per cent. Tests for malaria, syphilis, undulant fever and typhoid were negative. The urine was normal. No focus of infection was found. Pleurisy developed about two weeks after the onset of the first symptoms and a pleural tap was negative and recovery complete. At odd intervals chills and fever would return in one attack and he would be apparently well between them. Could this have been a syndrome precipitated by intensive training or is it possible for a focus of infection to remain "hidden" for so long a period with no other outward signs?

W. A. BALOGH, M.D., Dunellen, N. J.

ANSWER.—The data are, of course, insufficient to permit one to arrive at a diagnosis, but in answering the specific questions raised one would suggest that the illness was probably precipitated by the intensive training and incident exhaustion with a presumed "lowered resistance." On the other hand, certain experiments in animals have shown that extreme fatigue paradoxically seems to increase the resistance to deliberate infection. It is indeed possible for a focus of infection (not necessarily in the sites usually associated with the term) to exist. The history of fever and pleurisy suggests that such a focus may be tuberculous and studies with the roentgenograms, skin test with purified protein derivative, sedimentation rate of the red cells and repeated careful examinations should be made. The weight should be registered regularly. Other evidence of infection must also be sought, particularly in the urethra and prostate.

#### POSSIBLE ALLERGY TO CATGUT

To the Editor:—Several years ago a patient was operated on for streptococcal salpingitis, cystic ovaries and chronic appendicitis. A suspension of the uterus was also done. The sutures used were chromicized sheepgut, no silk or linen sutures being used, and clips were used to close the skin. Before this time she had no allergy of any sort, but since then, beginning about four months after the operation, she has had chronic hives, especially on the lower half of the body. She attributed these at first to potatoes and found some relief by abstinence from them. Lately the condition has become more severe, especially if clothing made of wool or partly of wool is worn and if lamb or mutton is eaten. Could she have developed an allergic reaction to the sutures left in the body? How could an extract or testing solution be made for a skin test? Since the operation she has become more obese; she weighed 185 pounds (84 Kg.) before and 200 pounds (91 Kg.) after it. Diet and small doses of thyroid brought this weight down to 175 pounds (79 Kg.) in several months.

M.D., Pennsylvania.

ANSWER.—The question of sensitivity to catgut is still in dispute. A number of clinical studies of probable catgut allergy have been reported (Hinton, J. W.: *Arch. Surg.* 33:197 [Aug.] 1936. Tripp, H. D.: *J. Indiana M. A.* 28:383 [Aug.] 1935. Kraissl, C. J.: *Surg., Gynec. & Obst.* 63:561 [Nov.] 1936). Animal experiments, however, have generally failed to confirm the claim that catgut is antigenic (Marconi, L.: *Rassegna internaz. di clin. e terap.* 14:3, 1933. Friagioni, P.: *Arch. ital. de chir.* 43:334, 1936). The antigenic relationship between catgut and sheep serum could not be demonstrated by Marchesani in animal experiments (*Ber. re. d. Versamml. d. Deutsche Epth. Gesellsch.* 49:233, 1932).

In the case mentioned the following considerations are against the urticaria being due to catgut: 1. Sensitization to chromicized catgut because of its relative resistance to digestion is even less likely than to ordinary catgut. 2. The intermission of four months before the development of urticaria is unlikely as an incubation period because of the length of time. 3. The relationship of wool, lamb or mutton to catgut (sheep intestine which has, however, been greatly altered in its preparation as chromicized catgut) is not established. Wool sensitive patients are not usually sensitive to lamb, and vice versa.

The other more common causes of urticaria (drug sensitization, food sensitization, endocrine disturbance, foci of infection) should be considered first in this patient. However, if it is

desired to prepare an extract of chromicized gut, it should be ground thoroughly in a mortar with sand, extracted with physiologic solution of sodium chloride for several days and sterilized by filtration through a bacterium retaining filter. The material may then be tried without dilution and in various dilutions (1:10, 1:100, 1:1,000) by the intradermal method in the patient. A number of "normals" should be tested likewise to ascertain that the extract in the concentration used is not irritating to the normal skin (false positive reaction).

#### REINJECTION OF ASCITIC FLUID IN CIRRHOSIS

To the Editor:—Is it an approved procedure to reinject intravenously in moderate sized doses (about 500 cc.) ascitic fluid removed in a case of portal cirrhosis? The fluid would be collected aseptically. Isn't the loss of the protein in the fluid, which in this case amounts to from 5 to 18 liters (quarts) every two weeks, a drain on the patient which might be lessened by reinjection?

M.D., Virginia.

ANSWER.—This procedure has been carried out in the past by several investigators in cases of cirrhotic ascites with conflicting results. Most ascitic fluid of this nature contains less than 1 per cent of protein and the colloid osmotic pressure is usually low. It is true that such a daily loss of protein is a serious drain on the patient's reserves; but many cases have been followed over long periods with frequent determination of the serum protein values at stated intervals and in spite of the large loss of protein in the ascitic accumulations these patients are able to keep the serum protein at a fairly constant though subnormal level. In order to get enough protein from ascitic fluid it would necessitate parenteral administration in extremely large amounts. Cumulative experience in this field seems to have demonstrated the fact that repeated blood transfusion and the administration of 6 per cent acacia will more favorably affect the protein content and colloid osmotic pressure than would the injection of protein by the method suggested.

#### NITROUS OXIDE ANALGESIA

To the Editor:—Do you recommend an anesthetic machine of the Ohio Analgesor type for minor operations such as opening an abscess? Ethyl chloride is all right for the skin but does not relieve the pain of probing. Would some type of glass container of chloroform as used in obstetrics for self administration give adequate relief from pain with safety?

ALEXANDER WINTER, M.D., New York.

ANSWER.—Many minor surgical procedures, such as opening abscesses, may be efficiently carried out under nitrous oxide analgesia. The Ohio Analgesor is a type of apparatus designed for producing nitrous oxide analgesia (not anesthesia) by means of self administration. This apparatus mixes nitrous oxide with air and should be operated by the patient. Attempts to produce anesthesia with this instrument will result in oxygen want. By self administration, satisfactory analgesia is produced in many cases.

Self administration of chloroform has been deemed unwise by many because of the toxicity of the drug even in small quantities. If the quantity of the drug administered is controlled carefully and adequately, it may be used with relative safety. Self administration, as suggested, does not offer adequate control of the quantity inhaled in the majority of cases.

No anesthetic agent, apparatus or technic can be recommended. However, individuals may be recommended for the administration of anesthetic agents. The safety of any drug or method in medicine is largely dependent on the doctor's knowledge of it.

#### COITUS DURING ANTISYPHILITIC TREATMENT

To the Editor:—I am treating a man and his wife for syphilis. Both patients have had two and a fraction courses of nearsphenamine (about nineteen injections) and one course of bismuth preparations. They intend to continue treatment. Is it possible or likely that one patient would be cured before the other and that the uncured partner would reinfect the other? No measures for prevention of infection have been used during intercourse. Is it necessary that coitus be curtailed? M.D., Illinois.

ANSWER.—When both husband and wife are infected with syphilis, no curtailment of intercourse is necessary except so far as contraceptive measures may be desirable for the prevention of pregnancy. It is unwise for a woman with early syphilis to undertake pregnancy until at least a year of treatment has been given.

It is improbable that one patient will be cured before the other and subsequently reinfect the uncured partner. It has happened that both partners have been cured and that one has subsequently been reinfecting from an outside source and has then reinfecting the other partner.

## INFRA-RED PHOTOGRAPHY AND MALIGNANT CONDITIONS

*To the Editor:*—In a recent article in Collier's the use of infra-red photography was mentioned as a means of determining the extent of inward growth of tumors appearing in or just beneath the skin. The author stated also that such means give an indication of possible malignant conditions. What is the status of such work? If it is of any value, experimental or otherwise, please outline the technique or cite references.

M.D., North Carolina.

**ANSWER.**—It is possible by means of infra-red photography to visualize the superficial veins in the skin of subcutaneous tissues. This procedure does not permit a distinction between a benign and a malignant tumor. In its present stage of development it has no value in the diagnosis of neoplastic diseases.

SIMILAC, ORANGE JUICE AND COD LIVER OIL  
IN INFANT FEEDING

*To the Editor:*—Since birth a baby has been on a diluted similac formula exclusively. Is this a satisfactory substitute for a whole milk formula over an extended period of time? When should orange juice and cod liver oil be started? The child is now 3 weeks old and has gained nicely.

ALVIN ROSENBERG, M.D., Morristown, N. J.

**ANSWER.**—Similac in dilutions as recommended at different ages by the manufacturer makes a good formula. It is a satisfactory substitute for a whole milk formula until about 4 or 5 months of age. Orange juice and cod liver oil should be started now, as the infant is nearing 4 weeks of age.

## ICE CREAM FOR CHILDREN

*To the Editor:*—What is considered the proper time to introduce ice cream into the diet of a child? I can find no satisfactory statement on this point in any books to which I have access.

M.D., New York.

**ANSWER.**—Ice cream is a frozen, sweetened milk product, most often made with the addition of some flavoring extract. If this frozen material is properly prepared and protected against spoiling, it may be given in small quantities to children starting at 18 months or 2 years of age. A caution should be urged that the product be of the purest quality.

## TESTES ATROPHY AND TESTICULAR EXTRACTS

*To the Editor:*—When testicular extracts are administered in the treatment of the benign prostate hypertrophy or chronic prostatitis is there any danger of producing a secondary atrophy of any of the component cells of the testis in the patient under treatment?

M.D., Idaho.

**ANSWER.**—There is probably no danger. In immature rats such substances cause severe testicular injury but in mature rats no such effects have been reported. No reports of damage to testes have been reported for man.

ACTION OF MAGNESIUM SULFATE SOLUTIONS  
SUBCUTANEOUSLY

*To the Editor:*—Please explain why a 50 per cent solution of magnesium sulfate, although hypertonic, is painless when injected subcutaneously.

M.D., Indiana.

**ANSWER.**—A solution of magnesium sulfate in the concentration of 0.8 per cent is capable of producing local anesthesia when injected subcutaneously. At this concentration it acts slowly. When the concentration is 50 per cent the action is almost instantaneous, the anesthesia being produced by the action of the drug on the nerve endings and the nerve trunks. Consequently a subcutaneous injection of a 50 per cent solution of magnesium sulfate is painless.

## THE SKELETON AND BODY WEIGHT

*To the Editor:*—To what degree is weight affected by difference in the weight of the skeleton? For instance, what difference in weight would one expect in three men of the same age and same height, one having a frame that would be called heavy, another medium and another light?

W. S. DOUGLAS, M.D., Lewiston, Idaho.

**ANSWER.**—These queries cannot as yet be answered categorically; there are not enough relevant observations. What may be said definitely is as follows:

The skeletons of persons who have died of prolonged exhaustive illness are as a rule lighter than those of persons of the same age and development who have not been so affected.

In senility the skeleton gradually loses in weight, and in some instances the eventual loss may be considerable. But there is little if any regularity to the process.

During adult life, under normal conditions, the weight of the skeleton is proportionate to the height and robustness of the person. But even here, as in all other features of the human body, there is a range of normal individual variation.

PARALYSIS OF ARM AFTER TIGHT BANDS  
OR BRACES

*To the Editor:*—What are the possible effects of shoulder braces or arm bands in causing "peripheral nerve lesions of the arm and forearm"? What procedures are indicated to prevent such injuries?

GREGORY SMITH, M.D., New York.

**ANSWER.**—Shoulder braces that are too tight may induce sensory and motor paralyzes of the extremity of varying degrees. "Crutch paralysis" is of the same character and may last for some weeks. The treatment consists of removal of the cause, such as too tight shoulder braces or bands, and complete recovery may be predicted.

## VEHICLE FOR BROMIDES AND BELLADONNA

*To the Editor:*—Can antipyrine, bromides and tincture of belladonna be combined in a single prescription for whooping cough? I have used the latter two together in a vehicle of syrup of citric acid and cinnamon water, which, however, does not make a pleasant tasting preparation. Could the three be combined in syrup of glycyrrhiza? Is there something better?

M.D., Iowa.

**ANSWER.**—Antipyrine, bromides and tincture of belladonna may be combined in a single prescription, and the syrup of glycyrrhiza makes a better vehicle for them, as far as disguising the taste is concerned, than does syrup of citric acid and cinnamon water. There is probably no better vehicle for these drugs than syrup of glycyrrhiza.

## FAMILIAL SPINAL SPASTIC PARAPLEGIA

*To the Editor:*—I should like information or references as to any arrestive or preventive medical treatment for familial spinal spastic paraplegia.

M.D., Pennsylvania.

**ANSWER.**—There is no known treatment that will arrest the course of this disorder. Like other familial diseases, it might ultimately be stamped out if those afflicted should be sterilized.

## HAVERHILL FEVER

*To the Editor:*—Who is equipped to do an agglutination test for Haverhill fever? Kindly give bibliography of this disease.

E. C. ALEXANDER, M.D., Castalia, Ohio.

**ANSWER.**—Agglutination tests for Haverhill fever can be done at the Division of Infectious Diseases, National Institute of Health, Washington, D. C. Dr. Place at the Boston City Hospital is also equipped to do this test. The following references give a good description of the disease:

- Scharles, F. H., and Seastone, C. V.: Haverhill Fever Following Rat Bite, *New England J. Med.* 211:711 (Oct. 18) 1934.  
Parker, Frederic, Jr., and Hudson, N. P.: The Etiology of Haverhill Fever (Erythema Arthriticum Epidemicum), *Am. J. Path.* 2:357 (Sept.) 1926.  
Place, E. H.; Sutton, L. E., Jr., and Willner, Otto: Erythema Arthriticum Epidemicum, Preliminary Report, *Boston M. & S. J.* 194:285 (Feb. 18) 1926.  
Hazard, J. B., and Goodkind, Robert: Haverhill Fever (Erythema Arthriticum Epidemicum), *THE JOURNAL*, Aug. 13, 1932, p. 534.

## GARLIC TO LOWER BLOOD PRESSURE

*To the Editor:*—Is the use of "garlic" of any value in lowering blood pressure in essential hypertension?

M.D., South Carolina.

**ANSWER.**—No.

## TREATMENT OF HEMANGIOMA

*To the Editor:*—With regard to "Treatment of Hemangioma," page 1683 of *THE JOURNAL*, Oct. 29, 1933, I should like to suggest a source of solid carbon dioxide available to any practitioner. Not having a cylinder to make carbon dioxide snow, I decided to use commercial dry ice and obtained some from my druggist. Cutting it into appropriate shapes and sizes, I have used it to cure successfully three hemangiomas. The first patient was a baby girl of six months with two pea sized hemangiomas, one in the center of the forehead and the other on the inner aspect of the thigh. The other patient was a girl of six with a smaller spider-like hemangioma on her temple. All were cured without scarring with one fifteen second application each.

FREDERIC SPEER, M.D., Kansas City, Kan.

Medical Examinations and Licensure

COMING EXAMINATIONS

STATE AND TERRITORIAL BOARDS

ALABAMA: Montgomery, Jan. 3-5 and June 20-22. Sec., Dr. J. N. Baker, 517 Dexter Ave., Montgomery.

ALASKA: Juneau, March 2. Sec., Dr. W. W. Council, Box 561, Juneau.

ARIZONA: *Basic Science*. Tucson, Dec. 20. Sec., Dr. Robert L. Nugent, Science Hall, University of Arizona, Tucson.

COLORADO: Denver, Jan. 4-6. Sec., Dr. Harvey W. Snyder, 831 Republic Bldg., Denver.

CONNECTICUT: *Basic Science*. New Haven, Feb. 11. Prerequisite to license examination. Address State Board of Healing Arts, 1895 Yale Station, New Haven.

DELAWARE: Dover, July 11-13. Sec., Medical Council of Delaware, Dr. Joseph S. McDaniel, 229 S. State St., Dover.

DISTRICT OF COLUMBIA: *Basic Science*. Washington, Dec. 26-27. *Medical*. Washington, Jan. 9-10. Sec., Commission on Licensure, Dr. George C. Ruhland, 203 District Bldg., Washington.

GEORGIA: Atlanta, June. Joint-Sec., State Examining Boards, Mr. R. C. Coleman, 111 State Capitol, Atlanta.

HAWAII: Honolulu, Jan. 9-12. Sec., Dr. James A. Morgan, 48 Young Bldg., Honolulu.

IDAHO: Boise, April 4-7. Dir., Bureau of Occupational License, Mr. D. B. Cruikshank, Rm. 355, State Capitol Bldg., Boise.

ILLINOIS: Chicago, Jan. 24-26. Superintendent of Registration, Department of Registration and Education, Mr. Homer J. Byrd, Springfield.

INDIANA: Indianapolis, June 20-22. Sec., Board of Medical Registration and Examination, Dr. J. W. Bowers, 301 State House, Indianapolis.

IOWA: *Basic Science*. Des Moines, Jan. 10. Dir., Division of License and Registration, Mr. H. W. Grefe, Capitol Bldg., Des Moines.

MICHIGAN: Ann Arbor and Detroit, June 14-16. Sec., Board of Registration in Medicine, Dr. J. Earl McIntyre, 100 W. Allegan St., Lansing.

MINNESOTA: *Basic Science*. Minneapolis, Jan. 3-4. Sec., Dr. J. Charney McKinley, 126 Millard Hall University of Minnesota, Minneapolis. *Medical*. Minneapolis, Jan. 17-19. Sec., Dr. Julian F. DuBois, 350 St. Peter St., St. Paul.

MONTANA: Helena, April 4-5. Sec., Dr. S. A. Cooney, 216 Power Block, Helena.

NEBRASKA: *Basic Science*. Omaha, Jan. 10-11. Dir., Bureau of Examining Boards, Mrs. Clark Perkins, State House, Lincoln.

NEVADA: *Reciprocity and oral examination*. Carson City, Feb. 6. Sec., Dr. John E. Worden, Capitol Bldg., Carson City.

NEW HAMPSHIRE: Concord, March 9-10. Sec., Board of Registration in Medicine, Dr. Fred E. Clow, State House, Concord.

NEW JERSEY: Trenton, June 20-21. Address, Dr. William L. Wilbur, 28 W. State St., Trenton.

NEW MEXICO: Santa Fe, April. Sec., Dr. Le Grand Ward, 135 Sena Plaza, Santa Fe.

NEW YORK: Albany, Buffalo, New York and Syracuse, Jan. 23-26. Chief, Bureau of Professional Examinations, Mr. Herbert J. Hamilton, 315 Education Bldg., Albany.

NORTH CAROLINA: Raleigh, June 19. Sec., Dr. William D. James, The Hamlet Hospital, Hamlet.

NORTH DAKOTA: Grand Forks, Jan. 3-6. Sec., Dr. G. M. Williamson, 4½ S. Third St., Grand Forks.

PENNSYLVANIA: Philadelphia, Jan. 3-7. Sec., Board of Medical Education and Licensure, Dr. James A. Newpher, 400 Education Bldg., Harrisburg.

PUERTO RICO: San Juan, March 7. Sec., Dr. O. Costa Mandry, Department of Health, San Juan.

RHODE ISLAND: Providence, Jan. 5-6. Chief, Division of Examiners, Mr. Robert D. Wholey, 366 State Office Bldg., Providence.

SOUTH DAKOTA: Pierre, Jan. 17-18. Director of Medical Licensure, Dr. B. A. Dyer, State Board of Health, Pierre.

VERMONT: Burlington, Feb. 14. Sec., Board of Medical Registration, Dr. W. Scott Nay, Underhill.

WASHINGTON: *Basic Science*. Seattle, Jan. 5-6. *Medical*. Seattle, Jan. 9-11. Dir., Department of Licenses, Mr. Harry C. Huse, Olympia.

WISCONSIN: Madison, Jan. 10-14. Sec., Dr. Henry J. Gramling, 2203 S. Layton Blvd., Milwaukee.

WYOMING: Cheyenne, Feb. 6. Sec., Dr. G. M. Anderson, Capit. Bldg., Cheyenne.

NATIONAL BOARD OF MEDICAL EXAMINERS  
SPECIAL BOARDS

Examinations of the National Board of Medical Examiners and Special Boards were published in THE JOURNAL, December 3, page 2141.

California June Examination

Dr. Charles B. Pinkham, secretary, California State Board of Medical Examiners, reports the written examination held at San Francisco, June 28-30, 1938. The examination covered nine subjects and included ninety questions. An average of 75 per cent was required to pass. One hundred and seventy-four candidates were examined, 172 of whom passed and two failed. The following schools were represented:

School	PASSED	Year Grad.	Per Cent
College of Medical Evangelists.....(1937)	78.9, 80.3, 80.7, 82.4, 83.7, 83.8, 84.2, 84.3, 85.1, 87, 87.7		77.7.
Stanford University School of Medicine.....(1938)	78.1, 78.2, 78.6, 79, 79.1, 79.4, 80.6, 80.7, 80.8, 81, 81.1, 81.2, 81.3, 81.3, 82, 82.1, 82.6, 82.6, 82.7, 82.8, 83, 83.3, 83.4, 83.4, 83.6, 83.8, 83.8, 84, 84.3, 84.3, 84.3, 84.6, 84.7, 85.1, 85.1, 85.1, 85.2, 85.3, 85.7, 86.1, 86.2, 86.6, 86.7, 86.8, 87.2, 87.2, 87.3, 88.3, 88.3, 89.3, 89.7, 92.1		76.6.

Book Notices

Health Insurance with Medical Care: The British Experience. By Douglass W. Orr, M.D., and Jean Walker Orr. Cloth. Price, \$2.50. Pp. 271. New York: Macmillan Company, 1938.

An entertaining style and numerous personal illustrations and observations make this book easy reading and illuminative of many sides of the problem of medical care in England. There is also a full treatment of the health activities in England largely based on the "Report on the British Health Services" by PEP (Political and Economic Planning) which presents a much more rounded picture than has been given in previous discussions.

The one contribution which the reader has a right to expect from the first extensive work on this subject by an American physician is an evaluation of the medical service given under health insurance. There is an elaborate attempt to give such an evaluation but it can scarcely be said to be successful.

The key to the entire attitude of the book is found in the statement concerning the sources of information. The authors state that they "arrived well armed with introductions to Big Names in English medicine" but that when they talked with an official of the British Medical Association and showed him their list of names he told them to "use them, but they aren't typical" and added "Let me give you names of men who are in general practice and who have insurance panels; they know the system inside and out." The authors congratulate themselves that "Thus Dr. Hill steered us around a common pit-fall." The naiveté of this observation is revealing to any one who has undertaken research in Europe concerning social institutions—he is always met by persons who are anxious to show him around and to guide him to the "proper" sources of information; these are often persons who will present the facts that will most surely support the system. That is clearly what happened to the authors of this book.

One of their first informants said he had never "heard of any one getting favors from the doctors or otherwise taking advantage of the scheme." It must have required careful isolation to keep from finding persons who have heard of such things, because they are complained of in official documents and in medical journals and are topics of conversation almost everywhere. In spite of being so carefully guarded, the investigators seem to have run into some of this information, for they say "Some doctors may be hoodwinked or cajoled into

certifying patients as incapable of work when in reality they should not be certified; some may find it profitable to be known as an 'easy doctor.' Of "sick visitors" we are told that "protection of funds against malingerers is the sole motive" of their visits. The familiar statement that few visits are made by regional medical officers "to inquire into excessive prescribing" and "in only six cases were fines imposed" fails to tell of the continuous flood of letters that are sent out by these regional medical officers politely and mildly warning physicians against such prescribing, and of course nothing is said of the many complaints in official reports, including those of the Ministry of Health, of the excessive prescribing as the result of the efforts of the physician to satisfy the demands of the patient for what British physicians in their own journals frequently admit are unnecessary medicines.

We are informed that "those who assert . . . that N. H. I. has increased the burden of sickness or dodged its responsibility by shifting it to the voluntary hospitals are misrepresenting the facts" (page 85). Yet we are told only two pages earlier that one investigator "found several two to three hundred bed hospitals with waiting lists of five to six hundred each." It must have been difficult even to ride along the roads of England and not see the repeated appeals for financial aid for hospitals and not to be told continuously that this was largely due to the increased burden created by national health insurance.

Perhaps the sharpest criticism which can be directed against the authors is that they base their main arguments as to the good quality of the medical service on the statements of patients. Certainly no physician in this country would accept the fact that a quack or distributor of nostrums can produce thousands of testimonials to the efficiency of his services or of the panacea sold as proof that these were of value to the patient. Yet that is essentially the sort of evidence which is offered here. Certainly, any physician undertaking an experiment with any method of treatment would be expected to produce vital statistics as one measure of the success of his plan. This measure is almost entirely omitted. The statement that "in Britain national concern over a maternal mortality rate which nevertheless averages considerably lower than that of the United States has provoked vigorous action" is not justified in view of the fact that the maternal mortality rate for England was 41.1 per thousand, for Wales 55.7 and for Scotland 63.7, as an average for the years 1924-1933 (Report on Maternal Mortality in Wales, Ministry of Health, London, 1937) while, in the United States, Rhode Island, Wisconsin, Minnesota and several other states show a rate approximately the same as that of England and nearly all the states at all comparable as to climate and racial conditions show rates lower than Wales or Scotland (Vital Statistics—Special Reports 5:43 [March 1] 1938, Department of Commerce, Bureau of the Census, Washington, D. C.). The impression is conveyed that a 40 per cent decline in the death rate during the last forty years in London is in some way related to sickness insurance. The decline in the United States has been even greater, without sickness insurance.

The authors quote "one of the most authoritative persons we interviewed" as concluding that "a panel of 2,500 is not too many for a doctor who has also some private practice." The statistics presented by the British Medical Association in a recent discussion of the capitation rates of payment for physicians showed that a little over five combined office and house calls per insured person were required annually. A panel of 2,500 would require 12,500 such services a year, or about forty for each working day. Considering that other studies of the British health insurance system have shown that these services are much more numerous in certain seasons than in others, we gain a rather peculiar idea of the standard of good service which the authors must have had in view. If we were to use their own figures, which are as much in error as some of their conclusions, this calculation would show much worse conditions, because they quote one of their medical authorities who thinks that panel patients average about ten visits a year. It is strange that authors who say so much about the thoroughness of their investigation and publish so long a list of

persons interviewed and so extensive a bibliography did not check these statements with available official statistics.

The bibliography itself requires some little attention. The list of "pamphlets and reports" consulted omits the "Report by the Government Actuary on an Examination of the Sickness and Disablement Experience of a Group of Approved Societies in the period 1921-27" and also the "Report on Incapacitating Sickness in the Insured Population of Scotland during the year 1st July 1934 to 30th June 1935." Is it possible that this omission is due to the fact that these official reports contradict many of the conclusions of the book as to the character of the service given? The entire bibliography is principally noteworthy for its complete omission of a considerable number of books that have been published in Great Britain criticizing health insurance.

There is frequent reference to the way in which disease is supposed to be prevented by early attendance under sickness insurance. No mention is made of Scottish and British reports which complain that immunization for diphtheria lags behind American standards. The authors could have found much information contradicting their statements as to this feature of British health insurance by an examination of the "First Lecture of a London Postgraduate Course" on "Preventive Treatment and the General Practitioner" contained in the Supplement to the *British Medical Journal* for April 1938 as well as in numerous other publications favorable to health insurance. The difficulty which it is claimed existed in finding any opponents or antagonistic critics might have been overcome by a consultation of the correspondence columns of the *British Medical Journal* and the *London Lancet*.

Finally, the attempt to show that British health insurance conforms to the "ten principles" of the American Medical Association is a heavy strain on both facts and logic.

*The Doctrine of Signatures: A Defence of Theory in Medicine.* By Scott Buchanan. Cloth. Price, \$2.75. Pp. 205. New York: Harcourt, Brace & Company; London: Kegan Paul, Trench, Trubner & Co., Ltd. 1938.

This volume in the International Library of Psychology, Philosophy and Scientific Method under the editorship of Prof. C. K. Ogden of Cambridge University belongs in section C devoted to scientific method. In it a metaphysician prescribes a program for physic. He reverts to the classics, in which philosophy had a leading part, and shows how Plato, Aristotle and Galen established the demonstrative power of form and matter in the biologic and medical sciences, and pleads that its rediscovery and reestablishment in modern signatures would reinvigorate medical thinking and open new paths for released speculative energies now thwarted by the lack of an organized philosophy of medicine.

The doctrine of signatures assumes that the data of science are potential symbols and it calls on the liberal arts and sciences to develop, clarify and realize the potentialities of human observations. The practice of these arts and sciences ends in the discovery and formulation of abstract form through which the data achieve their status as facts and scientific evidence. Forms are not only what the signatures signify, they are also the causes of things and therefore the proximate subject matter of science. The author proceeds to show how Plato, Aristotle and Galen elaborated this theme and he ultimately arrives at teleology in Galen. This he interprets as none other than the principle of causal determinism of modern science explained and stated in its fulness in the light of its metaphysical implications. He urges physicians to familiarize themselves with Galen's philosophy of medicine and his concept of physiology, which may be summed up in the title of one of his chapters, *The Human Body as Artist*.

He has a vision of a fusion of interests of medical men and philosophers in cooperation in establishing a new and more rational organization of scientific thought that has a basis broad enough to include in its scope not only the therapeutic approach to disease but the ramifications of this rationally organized science into legal, social and religious fields. The central position of the medical sciences with reference to man offers inviting prospects of leadership to the organizers of

such a system of thought. "Physic should recover its lost humanism and its intelligibility *quoad nos* as well as *secundum se*."

The proposed program includes the following suggestions, the accomplishment of which in a number of instances is at least in the early stages of formulation or even accomplishment: A critical evaluation of the sciences on which the medical arts depend with special attention to their past uses and their possible future relevance to an integrated science of physic. The abstraction and reformulation of the first principles in these sciences, showing their subordination or interdependence inside a single science. A digest of current working hypotheses, instruments and technics in medical research and practice. A study of measurement in science, numerical and non-numerical. The construction of a rational science and an empirical science of physic based on the preceding studies. A study of medical casuistry, the applied sciences of medicine, diagnosis, prognosis, therapy. A study of social medicine, epidemics, preventive medicine, creative medicine, and the proposed agencies for the medical control of society and the social control of medicine. A study of the possibilities of a permanent board for the continuous criticism and codification of medical knowledge. The last proposal has in it the element of undesirable bureaucracy. Growing sciences do not lend themselves to lasting codification. A certain amount of helpful criticism can be secured through annual topical summaries by experts. An excellent feature in the sciences is found in annual summer conferences in which specialists meet for discussion of live topics, and conflicting views are exposed to criticism. A splendid example is the recently established Mikkelsen Foundation of Bergen, Norway, endowed by the statesman-diplomat who composed the political differences between Norway and Sweden. Its policy is to foster annual international gatherings of specialists in the various fields of the sciences and other forms of human intellectual activity for several weeks of common residence, round table discussions and mutual criticism, but without any commitments or decisions by the assembled body. In the field of medicine the annual gatherings appear to be dominated by professional and social trends rather than by those of the programs outlined. Useful as such gatherings are, there still may be a place for the quiet contemplation and discussion of the basic scientific and metaphysical aspects of physic which the author of these prolegomena of medicine has thought out.

**Voice for Speech.** By Frederick Wesley Orr, Professor of English and Director of the Division of Speech at the University of Washington. Cloth. Price, \$2. Pp. 283, with 17 illustrations. New York & London: McGraw-Hill Book Company, Inc., 1938.

The author states that his aim is to contribute in a broad sense to the education of the student and at the same time to attack specifically his voice problems in a basic, fundamental way. At the beginning he points out that "if the author has learned anything during the past ten years in regard to vocal training, it has been the necessity of discovering the cause of the vocal difficulty, whether it be in the thinking, the lack of emotional control, objectionable personality traits, or a defective vocal apparatus; and once the cause has been discovered, working specifically for the removal of that cause." His approach is both physiologic and psychologic, and he believes that any corrective program must take into consideration the entire personality of the individual: the physical condition of his vocal apparatus, its responsiveness to stimulation, and the interferences—including abnormal personality traits and bad vocal habits—which prevent a normal functioning. For purposes of study he divides the vocal apparatus into four different systems; the coordinating system, the breathing system, the tone initiating system and the tone modulating system. He devotes a section to each system, discussing its anatomy and physiology, the abnormalities in its functioning, and the methods of discovering such abnormalities as well as methods of establishing the normal. The remaining four sections are devoted to quality, pitch, duration and strength, and modulating tone into speech sounds. The author suggests a series of tests to determine the reliability of the physical apparatus, especially the sense organs, and in each section he gives a diagnostic chart so that

a record may be kept of the results of the tests made. A number of exercises and reading selections are also given in each section. The book covers a great deal of ground and is written with admirable simplicity. However, the arrangement of the material, with its many repetitive divisions and subdivisions, is somewhat complicated, although at the same time it has merit in that each section is a complete unit and, if so desired, can be studied entirely apart from the rest of the material. All in all, the book is a sensible one and to those interested in the subject it should prove useful.

**Spectrochemical Abstracts 1933-1937: Being a 52 Page Bibliography with Abstracts of Over 200 Papers on Spectrochemical Analysis.** By F. Twyman, F.Inst.P., F.R.S. Paper. Price, 4s. Pp. 52. London: Adam Hilger Limited, 1938.

Twyman is a personality in the field of spectroscopy and applied optical measurement. His spectrochemical abstracts compile the literature of spectroscopy during 1933-1937. There are fifteen pages of author references arranged alphabetically. The remaining thirty-four pages are classified into biologic material, earths, electrodes, gases, industrial materials, liquids, metals and alloys, minerals, nonmetals, oxides, precipitates, soils, apparatus, methods, general, and a list of books. Any active worker in spectroscopy has his own filing system. The value of Twyman's references lies in his careful selection of manuscripts. There are, of course, certain omissions of literature data and larger treatises on spectroscopy, but they will be noted by the modern spectroscopist. In general, the little brochure is a handy tool on the table of any scientific worker making use of spectroscopic apparatus.

**New Creations in Human Beings.** By Louis Berman, M.D. Cloth. Price, \$3. Pp. 316. New York: Doubleday, Doran & Company, Inc., 1938.

Those men who read Berman's book on glands and personality will be prepared to find in this volume the same mixture of science and what David Starr Jordan used to call *sciosophy*, or the shadow of wisdom. Again in this book Berman's thesis is that internal secretions have much to do with determining the character of the individual, so much so in fact that in many cases criminality can be cured by treating the patient with mixtures of desiccated glands.

Although no expert clinician would question the fact that persons suffering from glandular disturbances are inclined to be nervous, psychopathic and unhappy, few real experts in the field of glandular diseases would care to go so far as Berman does. One difficulty with Berman is that he has his own ideas of what constitutes the clinical picture of disturbances of function in glands such as the parathyroid and adrenal, ideas that do not coincide with those of most scientific physicians today. For instance, on page 41 he tells of a child brought to him because of her shyness, impulsiveness, "explosive assaultiveness," nervousness, poor appetite, insomnia, laziness and dulness at school. Because Berman found a low blood calcium he states categorically that all the girl's troubles were due to parathyroid insufficiency. He does not go on to say how beautifully she reformed on dried parathyroids swallowed three times a day.

On page 253 one finds a description of a burglar who was in and out of reformatories and Sing Sing for eighteen years. He had a persistent thymus gland; "the adrenals were rated as quite deficient, and the gonads and sex glands as moderately deficient." Another bad boy running around and getting into mischief had hyperthyroidism, persistent thymus and marked parathyroid deficiency. According to Berman "There is now a fair degree of certainty that the criminal has a combination of glandular disturbances as the background of his antisocial behavior" and that the way to get at the criminal diathesis is to eradicate these glandular disturbances in childhood.

After many sad experiences in practice, the reviewer cannot help wondering whether Berman's case of hyperthyroidism was diagnosed from a basal reading of +10 per cent, and the hyperparathyroidism from one blood calcium of 9 mg. reported by a careless, poorly trained technician. The reviewer happens to have seen several cases of serious parathyroid disease but he cannot remember having noted in the patients any great disturbance in character and certainly there was no sign of crimi-

nality. Actually, the patients were complaining of such things as a painful caving-in of the spine, polyuria or tetany. Similarly, the many patients seen by the reviewer with an adrenal tumor or Addison's disease did not show any criminal tendencies.

Berman's answer would probably be that the symptoms that he observes are those of early, mild and unrecognized changes in the glands, but the objection to that is that, if certain symptoms are not found when the disease is severe and recognizable, how can any one prove that they are characteristic of the disease in those early stages in which most experts would refuse to accept the diagnosis? We fear this book should be sold over the fiction counter.

## Bureau of Legal Medicine and Legislation

### MEDICOLEGAL ABSTRACTS

**Malpractice: Failure to Discover Disunion of Fracture.**—The plaintiff, a woman about 55 years old, injured her left hip Dec. 18, 1932. The next day, on the advice of her attending physician, the defendant, she was removed to a hospital, where roentgenograms disclosed an intracapsular fracture of the neck of the left femur. The defendant reduced the fracture and immobilized her left leg in a splint. Roentgenograms taken five days later showed that the fracture had been reduced satisfactorily. On Jan. 12, 1933, roentgenograms disclosed a bony union and that the fragments of bone were still in good alignment. The patient left the hospital Jan. 23, 1933. Two weeks later, about seven weeks after the injury, the defendant removed the splint and advised the plaintiff to get up and walk with the assistance of crutches. When she attempted to do so she exclaimed "My God, my hip isn't together, I can feel it grating," and then fainted. Although she repeatedly informed the defendant that she believed her "leg was not together," he failed to take or advise the taking of another roentgenogram. On June 15, 1933, the plaintiff went to a clinic, where roentgenograms showed disunion of the fragments of bone. An operation was subsequently performed by another physician, an orthopedic surgeon, but the end result was that she had a 50 to 75 per cent disability. She then sued the defendant for malpractice, the trial court directed a verdict in favor of the physician, and the court of appeals, Summit County, Ohio, affirmed the judgment rendered on the directed verdict. The case was then certified to the Supreme Court of Ohio.

In the judgment of the Supreme Court, the evidence showed that the bony union which takes place between fragments of bone following a proper reduction of a fracture of the neck of the femur may be followed by a disunion through absorption within a few weeks. Such disunion can be disclosed only by a roentgenogram. Accepted medical practice requires that a roentgenogram should be taken at the time the absorption can reasonably be expected to have taken place, if at all, to determine whether that absorption has occurred. In the instant case the defendant failed to take or advise the taking of roentgenograms when the plaintiff complained to him that she felt a grating sensation when she attempted to walk and that the fragments of bone were not together, which was at about the time an absorption might be expected to have taken place. The court was of the opinion, therefore, that the evidence was sufficient to warrant submission to the jury of the issue of the defendant's negligence.

But, continued the court, in order to recover damages the plaintiff must prove not only negligence or unskilfulness on the part of the defendant but also that his negligence or unskilfulness was the proximate cause of her injury. The uniting of fragments of a broken bone must be accomplished by the healing processes of nature and essentially there is always the possibility that nature will fail to achieve the desired result even when the attending physician has done properly everything known to surgical science. Similarly, if the physician's treatment has been unskilful or negligent and the broken parts fail to unite, there is also the possibility that the disunion would have resulted even had the physician used due care and skill. Proximate

cause in the present case was an ultimate fact to be proved by the plaintiff and, before the trial court could submit the case to the jury, there must have been evidence which would warrant the jury in drawing an inference of probability. There was, the court said, no such evidence in the record. In fact, the evidence showed that there was a lesser probability rather than a greater that bony reunion would have taken place.

The evidence showed, the court said, that the chance of reunion of the fragments of the bone on a remanipulation and resetting was lost because the defendant had let the patient go on walking with crutches for three months without taking a roentgenogram or giving other attention to the fracture. There was no evidence, however, to show that reunion would have taken place even with the best of treatment. The evidence was therefore insufficient, in the opinion of the court, to support an inference that if the chance had not been lost through the fault of the defendant the injury concerning which the plaintiff complained would not have occurred. Loss of chance of recovery, standing alone, is not an injury from which damages will flow.

Accordingly, the Supreme Court affirmed the judgment in favor of the defendant physician.—*Kuhn v. Banker (Ohio)*, 13 N. E. (2d) 242.

**Workmen's Compensation Acts: Compensability of Death from Strangulation of Preexisting Nonindustrial Hernia.**—From the strain and effort of lifting sacks of material in the performance of his duties, a loop of intestine was forced into the sac of an inguinal hernia from which the deceased already suffered. There the intestine became strangulated. In the course of an operation to release the strangulation, a general anesthetic was administered. Pneumonia followed and death ensued. The industrial accident board awarded compensation to the widow and minor daughter of the deceased. The plaintiff in this case, the employer's insurance carrier, sued to set aside that award. The trial court entered judgment in favor of the plaintiff insurance company, and when that judgment was reversed by the court of civil appeals of the second supreme judicial district, Texas, the insurance company appealed to the Supreme Court of Texas.

According to the pleading, said the court, the injury sustained by the deceased was in final analysis the strangulation of a part of his intestine. This strangulation resulted from the strain of lifting the sacks of material. The strangulation and the ensuing consequences fall clearly within the statutory definition of "injury." The preexisting hernia was incidentally involved in the occurrence of such an injury, but it did not itself constitute the injury or result from it. Nothing appears in the statute, said the court, on which to found a reasonable conclusion that the legislature intended to impose the limitations laid down by it on claims based on hernia, on any injury where no hernia is involved except a preexisting hernia which does nothing more than furnish a condition in which the force which causes the injury operates.

The judgment of the court of civil appeals, reversing the trial court's judgment and remanding the cause for trial, was therefore affirmed.—*Actna Life Ins. Co. v. Liles et al. (Texas)*, 114 S. W. (2d) 534.

### COMING MEETINGS

- American Academy of Orthopedic Surgeons, Memphis, Tenn., Jan. 15-19.
- Dr. Carl E. Badgley, 1313 East Ann St., Ann Arbor, Mich., Secretary.
- American Association for the Study of Neoplastic Diseases, Baltimore, Dec. 28-30. Dr. Eugene R. Whitmore, 2139 Wyoming Avenue N.W., Washington, D. C., Secretary.
- American Student Health Association, New York, Dec. 29-30. Dr. Ruth E. Boynton, Students Health Service, University of Minnesota, Minneapolis, Secretary.
- Eastern Section, American Laryngological, Rhinological and Otolological Society, Boston, Jan. 11. Dr. Frank E. Kittredge, Masonic Temple, Nashua, N. H., Chairman.
- Middle Section, American Laryngological, Rhinological and Otolological Society, Sioux City, Iowa, Jan. 19-20. T. R. Gittins, Davidson Bldg., Sioux City, Iowa, Chairman.
- Southern Section, American Laryngological, Rhinological and Otolological Society, New Orleans, Jan. 14. Dr. Francis E. Lefebvre, Maison Blanche, New Orleans, Chairman.
- Western Section, American Laryngological, Rhinological and Otolological Society, Spokane, Wash., Jan. 29. Dr. Frederic G. Sprowl, Medical Arts Bldg., Spokane, Wash., Chairman.

## Current Medical Literature

### AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1928 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (\*) are abstracted below.

Standards for Maximal Reticulocyte Percentage After Intramuscular Liver Therapy in Pernicious Anemia. R. Isaacs and A. Friedman, Ann Arbor, Mich.—p. 718.

**Chronic Hypoglycemia.**—During a period of eighteen months Dorst observed sixty-two ambulatory patients who had low dextrose tolerance curves. From this it would seem that the existence of chronic hypoglycemia is far more common than is generally appreciated and that it frequently occurs in asthenic undernourished individuals who present the familiar picture of the "effort syndrome." The constantly low level of blood sugar may be responsible in part at least for the lack of vigor which characterizes these people, since the chief source of energy in mammalian metabolism is derived from the burning of carbohydrate. Patients with chronic hypoglycemia show a dextrose tolerance curve which remains in the fasting zone regardless of the ingestion of food and it is possible that under these conditions there is inadequate fuel to be suddenly expended in the form of energy. This syndrome must be differentiated from spontaneous hyperinsulinism. When treated with small doses of insulin (5 units before breakfast and 10 before lunch and dinner) a number of the patients with chronic hypoglycemia showed marked clinical improvement, an increase in the sense of well-being, gain in weight and increased appetite; concomitant with this improvement the dextrose tolerance curve returned to the usual normal configuration. The precise action of the insulin in effecting this change is not understood. The author suggests the possibility that the demobilization of hepatic glycogen is in some way inhibited and he hopes to establish this thesis by further investigation.

**Etiology, Death Rates and Bacteremia in Pneumonia.**—In this article Bullova and Gleich use the following terms to mean: infants as "children less than 2 years of age," children as "those from 2 years to puberty" and adults "all those beyond puberty." Only the ten commonest of the thirty-two Cooper types of pneumonia are considered. The total number of pneumococcal pneumonias was: infants 381, children 371 and adults 3,065. The ten types of pneumococci represented 63 per

cent of all pneumococcal pneumonias in infants, 78.8 per cent in children and 74.5 per cent in adults. The mortality for these ten types of pneumonia among adults was 26.9, infants 16.2 and children 4.1 per cent. In the pneumococcal pneumonias the blood was most frequently invaded in adults (23.5 per cent). The rate for infants was 6.7 and for children 4.1 per cent. In the positive blood culture cases, infants showed the highest death rate (83.3 per cent), adults 74.1 and children 25 per cent. The four important classifications of nonpneumococcal pneumonias represented 66.7 per cent of all nonpneumococcal pneumonias in infants, 84.3 in children and 76.6 per cent in adults. In these cases the death rate was 29.8 in adults, 21.2 in infants and 4.6 per cent in children. In the nonpneumococcal pneumonias, the blood was most frequently invaded in adults (16.1 per cent). In infants it was 4 per cent and for children 1.7 per cent. In the positive blood culture cases, infants showed the highest death rate (100 per cent), adults 95 per cent and children 75 per cent.

**Amphetamine Sulfate in Persistent Hiccup.**—Shaine found amphetamine sulfate to be of value in relieving two cases of persistent hiccup. In both cases it is apparent that amphetamine sulfate, perhaps through its action on smooth muscle, controlled the spastic condition responsible for the hiccup. The dose of amphetamine sulfate was from 10 to 20 mg. once or twice daily.

### Sulfanilamide and Gonocidal Power of Whole Blood.

—Keefer and Rantz show that the administration of sulfanilamide by mouth in adequate amounts to patients with gonococcal infection is followed by an increase in the bactericidal power of the blood for the gonococcus. That this is due to the presence of sulfanilamide and not to the development of specific antibodies was shown by giving the drug to noninfected individuals and by adding the drug directly to whole blood of individuals with and without antibodies. The addition of the drug to serum was as effective as adding it to whole blood, showing that cells and phagocytosis were not necessary for the killing of the gonococcus in these experiments. Heating the plasma to destroy normal antibody reactions did not affect the action of sulfanilamide on the gonococcus. When the drug is discontinued, the concentration in the blood declines rapidly so that within from forty-eight to seventy-two hours most of the sulfanilamide has disappeared. The exception to this is the presence of renal insufficiency. Under these conditions the blood may continue to show large amounts of sulfanilamide for many days. When sulfanilamide is added to ascitic broth there is evidence for a bacteriostatic effect except when small numbers of organisms are used in the original inoculum. Under these circumstances the organisms fail to survive. In the treatment of gonococcal infections maximal effects can be obtained by giving 5 Gm. of sulfanilamide daily and by keeping the sulfanilamide concentration of the blood at 5 mg. per hundred cubic centimeters of blood. The presence of sulfanilamide in the blood and the synovial fluid will aid in the destruction of organisms in the joints and it will also aid in preventing the spread of organisms from a local focus, but it will not cause complete sterilization

of a local focus of infection in the genital tract in every case. Before complete recovery can take place the defense mechanism of the body must increase or retain the capacity to destroy organisms in the local focus. The administration of the drug should be continued until immune bodies have developed.

**Venereal Fusospirochetosis.**—During studies on the etiology of pudendal infections von Haam encountered progressive and destructive ulcerations of the external genitalia which originated usually, but not exclusively, in the mucous membrane and exuded a copious, purulent, hemorrhagic discharge of penetrating fetid odor. Smears from the exudate showed much necrotic cellular material with numerous pus cells and an abundant amount of fusiform bacilli, spirochetes and vibrios, the characteristic flora of Vincent's infection of the mouth. Routine bacterial cultures demonstrated only a slight participation of the common pyogenic flora in the ulcerative processes, while other venereal diseases could be excluded by careful laboratory examination. The usual local antiseptic therapy did not influence the steadily progressive character of the ulcerations, which in some cases led to extensive mutilation of the external genitalia. The characteristic presence of Vincent's flora in the discharge and the absence of other demonstrative etiologic agents seemed sufficient proof that the lesions were caused by the group of fusospirochetal organisms. Among 622 patients examined in the diagnostic laboratory for venereal diseases established at the Charity Hospital in New Orleans, thirty-seven cases of primary fusospirochetal infection of the genitalia have been recognized. The Negro race, the male sex (twenty-three cases) and the age groups between 20 and 30 years were most frequently represented in the patients suffering from the infection. Intense local pain and penetrating foul discharge were the principal clinical manifestations. Constitutional symptoms were present in twelve patients and one patient died.

### American Review of Tuberculosis, New York

38: 531-650 (Nov.) 1938. Partial Index

- Body Section Radiography with Laminagraph in Pulmonary Disease. S. Moore, St. Louis.—p. 538.
- Mediastinal and Hilar Angiography in Pulmonary Disease: Preliminary Report. I. Steinberg and G. P. Robb, New York.—p. 557.

- \*Immunization Against Tuberculosis: Study of Essential Factors. M. I. Levine, P. Vogel and H. A. Rosenberg, New York.—p. 632.

**End Results of Thoracoplasty.**—To show how few private patients can be traced, Peters and Cornish are able to report on but seventy-eight cases out of a series of more than 300. There were forty patients on whom a complete thoracoplasty was performed, 21 per cent of whom became well (negative

sputum and cavity closed) while 54 per cent are dead. All these patients were hopelessly ill and would ultimately have died had it not been for the surgical intervention. None were able to work even part time. The others are living with positive sputum and open cavity no better than before operation and will ultimately die of tuberculosis. There were thirty-eight patients on whom a partial thoracoplasty was done, 50 per cent of whom are well (cavity closed and sputum negative) and 34 per cent are dead. The others still show positive sputum, open cavity and inability to work. They too will no doubt die of tuberculosis, but had thoracoplasty not been done all would have died of their disease. The indications for thoracoplasty are about the same as for pneumothorax. These end results, as well as others reported in the literature, prove that all patients who must otherwise die of their tuberculosis should be given the benefit of thoracoplasty if they offer a fighting chance for recovery. To do less is to sacrifice lives that might otherwise be saved. All those reported well have been so for from two to fifteen years.

**Immunization Against Tuberculosis.**—During the last eleven years a study on the efficacy of BCG vaccination against tuberculosis in children has been carried on in New York City by the Bureau of Laboratories of the Department of Health. Levine and his colleagues report on the methods used up to April 1, 1937, during which time 1,830 children of tuberculous families have been followed, of which 880 were vaccinated and 950 served as controls. In the course of these eleven years of study the importance of selecting adequate controls has been emphasized repeatedly. At the outset of the study an attempt was made to control the experiment by dividing the children into two equal groups, those vaccinated and those not vaccinated. This procedure (usually the children of cooperative parents) was followed from 1926 to Jan. 1, 1933. In all 955 children were studied, 435 of whom were vaccinated, when the procedure of selection was changed so that alternate children were vaccinated and the others served as controls. Under this selection 744 children were observed from Jan. 1, 1933, to Sept. 1, 1936, 383 being vaccinated and 361 held as controls. The results of BCG vaccination before alternate selection was sixteen deaths in the control and three deaths in the vaccinated group. The results of BCG vaccination after alternate selection was instituted was four deaths in the control and six in the vaccinated group. It would seem, therefore, that the manner of selecting cases for vaccination or as controls exerted a marked influence on the final results obtained. A complete study of the participating factors is to be the basis of a forthcoming article.

**Carbon Tetrachloride Poisoning.**—Peery cites three cases of accidental poisoning by carbon tetrachloride in man that have been studied clinically and at necropsy. The deaths resulted from ingestion of a "roach poison" containing a mixture of

carbon tetrachloride and ethylene dichloride, mistaken for an intoxicant. One victim died about eight hours after taking the drug and showed no definite lesions at necropsy. The second died about sixty-eight hours after ingesting the poison and at necropsy acute necrosis of the liver was observed. The third patient died 150 hours after poisoning and at necropsy active regeneration of lost liver cells was seen.

**Tissue Reactions to Natural Oils.**—In order to determine the reactions of the tissues of experimental animals to oils, Hass injected olive oil and cod liver oil subcutaneously, intramuscularly and intraperitoneally in doses of 0.5, 0.25, 0.1 and 0.05 cc. Old and young animals were used. The tissues were examined at intervals of one, two and three weeks after the injection of each oil. Olive oil persists in an unchanged state in the intercellular medium of the subcutaneous tissues over a period of three weeks. During the same interval cod liver oil is partly transformed into an amorphous homogeneous semisolid material. A part of this material is insoluble in water, alcohol and xylene. Some of the insoluble substance is acid fast. The study of the various fractions of the hydrolyzed oils and the methyl esters of the acid products of hydrolysis shows that the amorphous semisolid material is formed in the intercellular region only in the presence of unsaturated fatty acids or methyl esters of unsaturated fatty acids. An increase in the amount of this material is correlated with an increase in the average unsaturation of the fractions employed. An increase in the intensity of the inflammatory response is associated with an increase in the average unsaturation of the fraction introduced into the tissue spaces. An infiltration with eosinophils is prominent in the zones of reaction to several of the unsaturated fractions in contrast with the relative infrequency of these cells in the zones of reaction to saturated compounds. The numerical distribution of multinucleated giant cells in the regions of response to the unsaturated liquid compounds indicates that the amorphous semisolid material derived from these compounds is the only effective stimulus to giant cell formation. The liquid methyl esters of the saturated acids, in contrast to the glyceryl esters, are rapidly hydrolyzed in the intercellular environment.

The Management of Hypertension. H. J. Stewart, New York.—p. 681.

**Testis Hormones.**—Koch points out that at present six androgens have been found in nature and that four of them have been isolated from human urine. Only androsterone and dehydro-androsterone have been separated from the urine of normal men. Whether all the androgenic activity in these urines resides in these compounds or whether others contribute remains to be determined. Although normal women also excrete large amounts of androgenic material, its exact nature has not been determined. Thus far, pure androgen has not been separated from the urine of normal nonpregnant women. However, in the pregnant woman epiallopregnanolone-3,20 has been separated from the urine as one of the androgens. In pathologic urines there undoubtedly are varying amounts of androsterone and pregnanetriol-3,17,20 in addition to androsterone, dehydro-androsterone and many other possible compounds of androgenic character. The normal type of androgen may be increased in concentration in pathologic conditions. In view of the possibilities of complex mixtures existing in various urines in various proportions it is probable that future advances in the quantitative studies on urine will depend to a large extent on the ability to differentiate quantitatively between the different androgens. However, for the present one must be content with the estimation of the total androgenic activity in tissue, body fluids and excretions in attempts to correlate the quantitative information with various endocrine disturbances possibly involving the gonads.

**Infantilism, Webbed Neck and Cubitus Valgus.**—Turner believes that infantilism, webbing of the skin of the neck and deformity of the elbow (cubitus valgus) occurring in the same person is unusual and to his knowledge has not been reported previously. The individual signs are perhaps not uncommon. The seven female patients forming the basis of the author's report cannot be classified under the syndrome of Klippel-Feil, Sprengel's deformity or cervical Pott's disease, as the shortening of the neck is merely apparent, due to the webbing, and not real. There is no absence or fusion of the cervical spine in any of these patients. There is some lowering of the hairline on the back of the neck, but no marked limitation of motion. Torticollis, mirror movements, facial asymmetry and other signs and symptoms, such as difficulty in breathing or swallowing, and shortness of breath, are not present. There is no mental retardation. Deformity of the elbow, consisting of an increase in the carrying angle, or cubitus valgus, is constantly present. All of the author's patients present osseous and sexual retardation similar to that associated with hypo-antuitarism, or the Lorain-Levi type of dwarfism. The blood and urine of these patients were entirely within normal limits. Roentgenograms of the skull, cervical spine, elbow, wrist and pelvis revealed no abnormalities with the exception of demineralization and evidence of delayed union of the epiphyses in six patients. Treatment with pituitary growth hormones has been unsatisfactory. There was definite genital development following the administration of the anterior pituitary gonadotropic substance in the two patients treated.

**Gonadotropic Substance and Development of Human Uterus.**—Payne and Shelton encountered ten women with small uteri (a depth of less than 2 inches) during a period of twelve months. All had some menstrual disturbance when first seen. A gonadotropic extract derived from the anterior pituitary glands of either hogs or sheep was used. Secondary menstrual disturbances occurred in three women of the group: following an acute infection, a change in climate and environment and after a severe nervous shock. The endometrium obtained by biopsy at the beginning of treatment was atrophic

in all patients. Since there was a response to treatment in all but two of the women, it became apparent to the authors that they were dealing not only with a problem of uterine hypoplasia but also with gonadal insufficiency. In seven of the eight women who responded to treatment there was improvement in menstruation and the endometrium became more normal following injections of the gonadotropic substance. Following these injections the endometrium changed to a secretory type in four patients and one other woman became pregnant, suggesting that anterior lobe extracts may have an influence on ovulation. Uterine growth occurred in three patients, the uterine depth increased from  $1\frac{1}{4}$  to  $3\frac{1}{4}$ ,  $1\frac{3}{8}$  to 3 and  $1\frac{1}{2}$  to  $2\frac{1}{4}$  inches respectively in each woman. It is impossible to draw definite conclusions, but it appears that the anterior pituitary elaborates a substance which stimulates the gonads, including an influence on ovulation and in some cases on uterine growth. Uterine development follows its administration.

**Milk Sickness.**—Gowen presents a review of the literature on milk sickness or "trembles." This condition is due to trematol, one of the toxic constituents of white snakeroot (*Eupatorium urticaefolium*). Milk sickness in man and "trembles" in domestic animals are identical. Animals acquire the disease by eating white snakeroot. Man acquires the disease by consuming milk or milk products from animals that have been eating the plant. Pasteurization does not destroy the poisonous properties. Trembles appear only in pastured animals. In every outbreak investigated by the author the animals had been turned into a wooded area, owing to lack of any other means of nourishment. The symptoms of milk sickness most commonly described and seemingly characteristic in order of occurrence are weakness or prostration, pernicious vomiting, severe constipation and epigastric pain. The temperature is characteristically normal or subnormal. Muscular pains are common. There is marked thirst, the urine is scanty, frequently acetone is found, and the breath has a distinct odor of acetone. Flushed cheeks and undue redness of the lips and tongue are not infrequent. Swelling of the tongue is commonly experienced by the patient. In fatal cases, coma and convulsions precede death. In patients who recover, weakness persists for days, weeks or even months, depending on the initial severity of the illness. Seemingly recovered patients may relapse if undue physical exertion is practiced too soon. In the author's twenty-one patients (two died) there was a direct relationship between the quantity of milk or milk products consumed and the severity of the disease. In general, treatment consists of saline purgation, fluids, alkalis by mouth, dextrose intravenously and enemas. The old remedy of brandy and honey finds some basis in the statement of Hardin, who says:

"The administration of alcohol causes an ester of trematol to be formed which is less toxic. If the patient becomes overheated before the ester is excreted, a hydrolysis of the ester occurs, liberating the poison."

**Multiple Idiopathic Hemorrhagic Sarcoma.**—Becker and Thatcher discuss the various designations and theories of the origin and etiology of Kaposi's sarcoma. The disease is seen predominantly in Italians and Jews. Incidence late in life with the peak at 70 years suggests neoplastic rather than infectious origin. In most cases the lesions have their onset on the lower extremities. Two cases are presented, one of which ended fatally, with true sarcoma formation. The injection of material from a benign lesion into a patient and a rabbit did not cause the formation of a tumor. The most logical explanation of Kaposi's sarcoma is that it is a multicentric benign neoplasm originating in the perithelial tissue from embryonic mesenchymal cells (lymphocytoid cells of Marchand), which results in a type of cell growth unique for the disease. After a period of years, the cells may undergo malignant degeneration, producing true sarcoma, resulting in metastasis and death. Metastasis by way of the lymphatics in contrast to hematogenous metastasis of most nonlymphocytic sarcomas may be construed as evidence of the lymphocytoid origin of the disease.

**Sciatic Pain from Protruded Intervertebral Disks.**—Love and his colleagues believe that many persons who are suffering from persistent or recurrent attacks of sciatic pain are harboring a protruded intervertebral disk, removal of which will result in dramatic relief of the symptoms. Intervertebral disks may be protruded as a result of an accident or of unusual stress or strain, such as lifting a heavy object. Although any one of the disks may be protruded, those most commonly subjected to this accident are in the lumbar region. The fourth and fifth (lumbosacral) disks are most frequently the cause of the patient's disability. The chief symptoms in cases of protrusion of intervertebral disks are root pain. Since the protrusion most often occurs in the lumbar region, the chief complaint is of pain low in the back and of sciatic pain, usually unilateral. On examination, Lasègue's test (raising the

straight leg) is usually positive and often the achilles tendon reflex on the involved side is diminished or absent. Because of the cases in which values for total protein in the cerebrospinal fluid are normal or low, the authors employ a reversed Queckenstedt test, which is helpful in the diagnosis of lumbar protrusions. This test is based on essentially the same principles as the usual Queckenstedt test, except that the increase in intraspinal pressure in the caudal sac is produced by the extradural injection of a 1 per cent solution of procaine hydrochloride whereas in the Queckenstedt test the pressure comes from within, when the return vascular circulation (internal jugular veins) is obstructed. One of the most important results of this test is the patient's reaction to compression of the cauda equina by the extradural solution. In case of a lesion involving one or more roots of the cauda equina, compression of the caudal sac produces excruciating pain in the involved root. If the value for total protein is normal or low, the reversed Queckenstedt test should be positive before the diagnosis of protruded disk is made. The diagnosis is confirmed and the protruded disk is identified by x-ray examination, after subarachnoid injection of 5 cc. of iodized oil between the spinous processes of the third and fourth lumbar vertebrae. If, on x-ray examination, a persistent defect characteristic of protruded disk is noted and if a lesion at that level could account for the patient's pain, surgical removal of the protruded portion of the disk is indicated. The operative procedure consists of laminectomy and removal, either extradural or transdural, of the protruded portion of the disk. The iodized oil is removed at the time of laminectomy. Fixation of the spine is not necessary. In more than 150 cases the authors have not found it necessary or advisable to perform fusion. The patients are treated postoperatively as if they had undergone simple laminectomy for tumors of the spinal cord. They are kept in bed twelve days and are allowed to leave the hospital on the fourteenth day and to return to their homes three weeks following operation. They are advised to refrain from heavy lifting and straining for at least three months.

**Anesthetic Effects of Cyclopropane.**—By experimenting on a rabbit and cats, Henderson found that both monochlorocyclopropane and dichlorocyclopropane are not suitable for anesthesia, as they cause irritation of the lungs. Cats forced to full saturation with cyclopropane take up large quantities

of gas, certainly more than 100 cc. per kilogram, and in some cases at least 150; similarly animals receiving methyl cyclopropane absorbed, under similar conditions, equal amounts in spite of its greater anesthetic potency. The evidence from the chlorinated cyclo compounds strongly suggests that substituted cyclopropanes are unstable in the body.

**Estrogen in Atrophic Rhinitis.**—Blaisdell states that estrogenic substances were first used in cases of atrophic rhinitis in the outpatient department of the Eye and Ear Infirmary on Aug. 1, 1937. A series of sixty cases is presented, divided into two groups; group 1 consists of patients with an onset (true atrophic rhinitis) before 20 years of age and group 2 is made up of patients with onset (secondary atrophic rhinitis) of symptoms after 20 years of age. There was clinical improvement, as shown by diminution of crusts and odor in 86.4 per cent of the patients in group 1 and improvement of all patients in group 2. Because of its wide variety of effects on the body, aside from its function as a sex hormone, estrogen, properly used, is one of the greatest weapons for combating diseases and physiologic conditions which heretofore have been obscure. Besides acting as a hormone estrogen acts also like a drug and its action is farther reaching than insulin, more powerful than epinephrine and more spectacular than ergot. As the study of this substance progresses, its exact place in the armamentarium of the otolaryngologist will undoubtedly be found. The relationship

between menstrual abnormalities and atrophic rhinitis should be undertaken by a gynecologist. The exact mechanism by which estrogen acts on the nose is not known and the extent of changes in the mucosa, as well as the permanence of the improvement clinically, can be determined only after years of carefully studying these cases.

**Type I Pneumococcus Pneumonia.**—During a period of twenty-five months 2,293 cases of type I pneumococcus pneumonia occurred in New York State exclusive of New York City. Rogers and Gooch discuss the 2,027 cases that were treated with concentrated type I antipneumococcus horse serum. Age had a direct influence on prognosis in the patients treated with serum as well as those not treated with it. Sex apparently influences morbidity but not mortality, save through its relationship to pregnancy. The data suggest that pregnancy may prove to be a factor predisposing to pneumonia and that the last four months of pregnancy most seriously influence the prognosis. The seriousness of bacteremia as reported by many other observers has been corroborated. The mortality rises in direct relation to the duration of the disease at the time treatment is started. Among 544 patients treated on or before the fourth day of illness the fatality rate was 15.8 per cent, as contrasted with 33.9 per cent for 183 patients receiving treatment later than on the fourth day of illness. Of the 544 patients, 251 received less than 100,000 units of serum and 17.5 per cent of them died; 293 received 100,000 units or more and 14.3 per cent of them died. This does not offer impressive evidence in favor of large dosage. However, if the group of 293 patients is further analyzed it is found that only sixty-

six of them received what might be termed "intensive" treatment, that is to say received all their serum within a period of twenty-four hours. Of these sixty-six patients only 6.1 per cent died, while of the 227 patients who received a similar amount of serum over more than twenty-four hours, 16.7 per cent died. The use of type I serum in the treatment of improperly typed cases, untyped cases or cases of heterologous types is discouraged. Of 129 such reports (not included in the 2,027 patients in the present series) the crude case fatality rate was 28.6 per cent.

**Lung Abscess Treated with Sulfanilamide.**—Murphy and Frere successfully treated a case of abscess of the lung caused by the hemolytic streptococcus with sulfanilamide. They believe that the use of the drug in their case caused immediate symptomatic and clinical improvement and perhaps

shortened the duration of the disease. When hemolytic streptococcus infection is found in the acute stage of pulmonary suppuration sulfanilamide is worthy of trial, provided no contraindications exist.

**Dinicotinic Acid in Pellagra in Relapse.**—Vilter and her associates used dimethyl dinicotinic acid (2,6-dimethylpyridine-3,5-dicarboxylic acid) or dinicotinic acid (3,5-pyridine dicarboxylic acid) in treating nine pellagrins in relapse and two nonpellagrous persons. These patients received orally from 500 to 1,000 mg. of the acid daily. Each acid, although soluble with difficulty, was completely dissolved in water before administration. The nine pellagrins were severely ill. Some temporary improvement was observed in five of the patients, the response being characterized by an increased feeling of well-being and a partial decrease in the fiery redness of the tongue. The subsequent administration of nicotinic acid, however, elicited a more complete response. The physiologic response to these drugs was quite different from the response to nicotinic acid. Neither oral nor intravenous administration has been found to produce the flushing reaction and rise in cutaneous temperature which occur after similar doses of nicotinic acid. Observations show that 2,6-dimethyl dinicotinic acid and dinicotinic acid have only a partial beneficial effect on pellagra in relapse and they should not be used as a substitute for nicotinic acid. The authors feel that protein deficiency in pellagra is of more importance in the syndrome of pellagra than is currently stressed and that perhaps a close interrelationship exists between protein metabolism and the role of nicotinic acid. At any rate a well balanced high caloric diet should be administered simultaneously with the nicotinic acid.

### Comparison of Preparations Used for Treating Burns.

—Terrell gives the composition of foille (0.14 per cent of potassium iodide, 0.25 of calcium iodide, 0.39 of calcium soap, 0.02 of calcium thiosulfate, 0.086 of calcium sulfite, 0.1 of oxyquinoline sulfate, 1.4 of ethyl alcohol by volume, 2.8 of phenol, 1.3 of ethyl aminobenzoate, 3.4 water, 90.11 of vegetable oil and sulfur and glycerin present) used in the prolonged treatment of burns. It is not toxic nor does it cause any detrimental systemic reactions. Its formula has been clinically tested with reference to analgesic, antiseptic and healing properties. Dogs have been used for experimental purposes. It has been used on human patients to a sufficient extent to warrant its recommendation in the treatment of all recent wounds and burns. It has been found safe to use in extensive as well as minor burns. The preparation has been tested on several occasions and found to have a low phenol coefficient, but in spite of this and its phenol content it has been proved that it is not injurious to the tissues when used in concentrated form. A thick layer of the medication is applied and a sterile dressing is placed over the wound. The wound is kept constantly bathed with the emulsion for forty-eight hours; then the dressing is removed and the preparation is reapplied. Thereafter, two or three applications are required each day until healing is complete. Experimentally, the burns of dogs treated with it healed much more rapidly and with considerably less discomfort than those treated with 10 per cent tannic acid or with either of two proprietary tannic acid preparations. The preparation offers a much shorter convalescence to the patient, with more comfort and less scarring, without the danger of toxic manifestations.

**Bacteriophage of Bacterium Coli.**—The studies performed by Merling-Eisenberg demonstrate the particulate nature of the bacteriophage of Bacterium coli. They point in the same direction as experiments of Elford, Andrewes and Tang (1936) and of McIntosh and Selbie (1937), who have shown by centrifugation that the bacteriophage action is bound to an agent of particulate nature. Because of their small size the bacteriophage bodies are not visible in transmitted light or stained preparations, which were the methods used by Wollmann (1925). d'Herelle (1926) has not observed any motion of the bodies within the bacterial cells, and he also reports only between fifteen and twenty-five bodies released from one bacterium. This is no doubt due to the optical system which he has employed. It obviously enabled him to perceive only the coarser granulate disintegration of the membrane into from fifteen to twenty-five particles, but not the ten times greater number of the much fainter bacteriophage bodies. The bacteriophage is distinguished from non-specific particles and its size is found to be 25 millimicrons.

**Significance of Blood Vitamin B<sub>1</sub>.**—Rowlands and Wilkinson established that the phycomyces test, based on Schöpfer's discovery (1935) that the growth of the mold *Phycomyces blakesleeanus* was proportional within certain limits to the amount of vitamin B<sub>1</sub> present in the medium, is a fairly reliable method of estimating vitamin B<sub>1</sub>. They determined the standard range for normal blood, taken from healthy members of the departmental staff, who gave figures ranging between 6.5 and 16.5 micrograms per hundred cubic centimeters of blood. Estimations were also carried out on a series of patients suffering

from alcoholic neuritis, nonalcoholic polyneuritis, subacute combined degeneration, diabetic neuritis, nutritional neuritis, anemias, and cardiovascular, renal and endocrine diseases. The investigations seem to show that gross vitamin B<sub>1</sub> deficiency is rare in England. This is not unexpected, since the daily requirement for the normal person is about 500 international units (1 mg. of pure vitamin B<sub>1</sub>): vitamin B<sub>1</sub> has a very wide distribution in foodstuffs and it is therefore almost impossible for the intake to be inadequate with a reasonable diet. This is in contrast to the position with vitamin C, the distribution of which is restricted to certain types of food. Nevertheless, vitamin B<sub>1</sub> deficiency may arise from an inadequate supply, inadequate absorption, inadequate utilization or through its destruction in the alimentary tract. In many of these deficiencies an inadequate dietetic intake leads to anatomic or physiologic changes within the intestine and then to diminished absorption, which in turn leads to further disorder of the intestinal function. Moreover, some balance between the specific nutritional elements, such as iron and vitamin B<sub>1</sub>, may be necessary. The only conditions in which a gross deficiency of vitamin B<sub>1</sub> was found were alcoholic neuritis, nutritional neuritis, scurvy and malnutrition. In these cases definite improvement followed the administration of vitamin B<sub>1</sub> (and vitamin C in the scorbutic patient). A partial deficiency was observed in simple achlorhydric anemia. The cases of subacute combined degeneration of the spinal cord gave normal figures; therefore the poor therapeutic results following the administration of vitamin B<sub>1</sub> obtained by workers in this field are not surprising. Similarly, the vitamin has not proved of much value in polyneuritis other than the alcoholic, gestational and nutritional forms. This observation corresponds with the values for blood vitamin B<sub>1</sub> found in this series. It appears, therefore, that the changes in the nervous system in these conditions, though clinically similar to those reported in beriberi, have a different etiology and are not associated with vitamin B<sub>1</sub> deficiency. There is no clinical evidence that vitamin B<sub>1</sub> is concerned in hemopoiesis, and this is corroborated by the normal figures given by this test in the uncomplicated primary anemias.

#### Suppression of Lactation by Oral Estrogen Therapy.

—Foss and Phillips state that experience in a few cases of acromegaly and thyrotoxicosis when attempting to inhibit the function of the anterior pituitary in human beings (Foss, 1937), together with Zondek's statement (1936) regarding the quantity of estrogen necessary to retard growth and gonadotropic function in rats, makes it difficult to realize that oral theelin in doses of from 20,000 to 30,000 international units given over a period of from two to six days can inhibit a function of the anterior pituitary. Normally this is held in check only by massive amounts of estrogen and/or progesterone in the placenta. It is much more possible, in the authors' opinion, that theelin acts specifically on the mammary gland, in some way preventing the action of the lactogenic hormone of the anterior pituitary or even by direct antagonism. At present an explanation of this clinical observation cannot be ventured. It is unlikely that such small doses will in any way influence the chemical constitution of human milk.

**Urea Clearance Test in Pregnancy.**—Brown presents the results of 671 urea clearance tests performed on 243 pregnant women. The urea clearance test was first determined for normal pregnant women and then tests were made both before and after

delivery on women with toxemia and on some patients who had pyelitis of pregnancy. A normal clearance test does not necessarily mean a normal kidney, as the test may be normal until from two thirds to three fourths of the renal tissue has been rendered functionless and also the clearance value is influenced by an alteration in the circulation rate and the supply of oxygen to the kidneys so that the results are lowered by severe anemia and cardiac decompensation. A low clearance value in an apparently well patient should be repeated and it must always be kept in mind that variations of less than 20 per cent are of no significance. The clearance results in the present series were less constant after than before delivery. Harrison says that in severe renal damage the clearance is more fixed than in normal persons. Each patient, therefore, must be considered separately. The urea clearance test extends but never replaces clinical investigation. The differential diagnosis between preeclamptic toxemia, chronic nephritis and essential hypertension is made much easier by the urea clearance test. Before delivery a high value excludes chronic nephritis and if the blood pressure remains high with little other evidence of toxemia and a high clearance the case is probably one of essential hypertension. If the clearance is low the result is of no value in pregnancy in the differentiation of preeclamptic toxemia, chronic nephritis and essential hypertension but the result after delivery is of great value—most patients suffering from preeclamptic toxemia show a rapid rise within a week or two of delivery, while in chronic nephritis the percentage rise is much less and the clearance never reaches a normal level. The follow-up of patients shows that if the clearance is high during the toxemia the prognosis is good even if the degree of toxemia is clinically severe, and the same may be said if the clearance rises to more than 100 per cent within a week or so of delivery even if the clinical condition lags behind. The clearance test is of most value several months after delivery when low tests show definite renal damage at a time when clinical signs may be slight or absent, although possibly on repeated clinical examination some evidence may be found in practically all cases. A low urea clearance is sufficient in the author's opinion to forbid a future pregnancy for at least two years, when further clinical examination and the clearance test should be repeated. Stander, Ashton and Cadden think that a urea clearance below 80 per cent is strongly suggestive of renal damage; therefore a further pregnancy is not wise. The clearance test is also useful during the treatment of toxemia; if the test is rising or remaining stationary, conservative treatment can be continued with confidence.

**The Human Fetal Electrocardiogram.**—Using a thermionic valve electrocardiograph susceptible of high amplification, Bell obtained electrocardiograms when leads were taken from the abdomen of pregnant women which show in some cases waves which are almost certainly fetal in origin. The evidence supporting the fetal origin is that the direction of the fetal deflection depends on the presentation (vertex or breech) and in a case of twin pregnancy two sets of deflections were obtained. Of thirty-three pregnant women examined in the last two months of pregnancy about one third showed positive results, but the other two thirds did not show any wave on the electrocardiogram which could be definitely recognized as fetal. It is suggested that the failure to secure positive results in all the electrocardiograms is due partly to differences in the electrical properties of the abdominal wall and partly to the electrical disturbances produced by the abdominal muscles, and not to insufficient sensitivity of the apparatus.

**Oxygen Therapy.**—Christie states that there are broad principles which must be appreciated if oxygen is to be used with understanding. The first principle concerned is that blood flowing through a healthy lung is more or less completely saturated with oxygen. The second principle is that cyanosis or lack of

oxygen does not cause dyspnea. The relief of dyspnea is of no significance in determining the value of oxygen therapy. The third principle is that if oxygen is given at all it should be given continuously. To give oxygen once every two hours to a patient with bronchopneumonia may be equivalent to placing him on top of Mount Everest and bringing him back to sea level every two hours for a "brcather." Most authorities are agreed that the intermittent administration of oxygen is probably worse than useless. Anoxemia can embarrass the heart of a healthy person; therefore the life of a patient with bronchopneumonia or acute pulmonary edema may depend on the efficient administration of oxygen. The indiscriminate administration of oxygen to any patient who is cyanosed and acutely ill is in part responsible for the conflicting evidence on the value of oxygen therapy. Oxygen should be given only when it is reasonable to expect that it will relieve the anoxemia. When cyanosis is due to localized consolidation or to localized collapse of the lung, it can seldom be relieved by oxygen. When cyanosis is due to a generalized impairment of aeration or to an inflammatory process scattered throughout the lung, oxygen, if properly given, should relieve cyanosis. An adequate supply of oxygen is as important as the method used for its administration. The most satisfactory methods for the administration of oxygen are the nasal catheter, the nasal mask and the oxygen tent. The nasal catheter is often too uncomfortable for continuous use if oxygen is given in amounts adequate for an adult. In infants the catheter may be satisfactory. The nasal mask is efficient, comfortable and inexpensive. A nasal mask for oxygen administration is described that combines efficiency with simplicity of operation and assures the comfort of the patient.

**Rickettsioses of South Africa.**—Pijper and Crocker believe that the three South African rickettsioses (tick-bite fever, murine or rat-flea or sporadic typhus and louse typhus) have been insufficiently studied, especially as regards their relationship with rickettsioses of other countries. Cross immunity tests have been performed only between tick-bite fever and spotted fever, with quite negative results, and by means of immune serum it has been shown that tick-bite fever and Rocky Mountain spotted fever probably have little in common. The need for further work in this and other directions is stressed, because there is evidence that the three South African rickettsioses form a group by themselves, possessing closer affinities

with one another than with rickettsioses of other countries. The virus of tick-bite fever is not filtrable, does not produce lesions in rabbit's eyes and the authors were unable to cultivate it on the chorio-allantoic membrane. A brief experiment showed that heartwater and tick-bite fever have nothing in common, although the two can be conveyed by the same tick. The contention that South African epidemic typhus is not identical with classic typhus is based on the results of Weil-Felix tests on patients: lower titer of X 19, good agglutination of X 2 in many cases, sometimes agglutination of X K. The authors have now confirmed this serologic difference by studying the agglutinin titers of a large number of rabbits infected with their Basutoland strain of epidemic typhus. In sporadic typhus in South Africa a virus was found that proved to be immunologically identical with a virus in rats. It protected against tick-bite fever but not against epidemic typhus. Epidemic typhus gives protection against this virus, as it does against tick-bite fever. The authors have now studied the agglutinin curves of several cases of this sporadic typhus and confirm in detail previous observations: agglutination of both X 19 and X 2 and sometimes also of X K. This sporadic form of typhus dies out in guinea pigs when brain injections are used; the epidemic form can be kept going indefinitely by this method.

#### Sodium Carbonate for Concentrating Tubercle Bacilli.

—T'ang examined 481 specimens of sputum from patients known to be suffering from pulmonary tuberculosis both by Petroff's 3 per cent sodium hydroxide method and by the sodium carbonate method. (Sodium carbonate in a solution of 7 per cent, allowed to act on the sputum for thirty minutes at a temperature of 65 C., is recommended to replace sodium hydroxide.) Other sputums (132) were examined by the direct smear method made from selected portions of the whole sample before being divided into two portions and further examined by the two concentration methods. It was found that sodium hydroxide concentration revealed only 4 per cent more positive sputums than direct smears, whereas the sodium carbonate method added 26 per cent. Bacilli are found more readily and in larger numbers after sodium carbonate concentration than in direct smears or after sodium hydroxide concentration. A more critical study of established methods of sputum examination was made on five sputums known to contain tubercle bacilli in small numbers. After the preparation of two direct smears from carefully selected particles of the crude sputum, it was divided into four equal portions. One portion of each sputum was treated by one of the four following methods: Pottenger's dilution-flotation, antiformin digestion, Petroff's sodium hydroxide concentration and the sodium carbonate concentration. Two smears of as nearly as possible the same size and thickness were made from each preparation and stained by the Ziehl-Neelsen method. It is probable that actually greater numbers of bacilli were seen after concentration by the sodium carbonate method than after dilution and flotation, as by the former method clumping of bacilli was commonly observed, whereas an even distribution of isolated bacilli was obtained by the latter method. The strongest recommendation for the use of sodium carbonate comes from a consideration that in the year 1936, when sodium carbonate was first used for concentration, the percentage of positive results increased by 7 per cent. During this year there was an increase in the total number of specimens examined. This was not due only to the fact that more patients were being seen but also to repeated examinations of carefully collected specimens of sputum from patients whose sputums were previously reported negative for tubercle bacilli.

 Sterility Due Principally to Chronic Gonorrhea. C. Bécère and Elie François.—p. 1525.  
 Ouabain Arnaud. C. Dimitracoff.—p. 1527.

**Epilepsy in Cerebral Tumors.**—Chavany and Placa state that epilepsy may appear either in typical or in somewhat abnormal forms during any phase of the clinical evolution of cerebral tumors. On the basis of personal observations in hundreds of cases they encountered it in about 15 per cent of the cases, whereas other investigators give percentages of 21, 30 and even 41. After a brief review of the literature the authors point out that epilepsy can be observed as a secondary sign, connected with ventricular dilatation or cerebral edema, in all forms of cerebral tumors. It appears in three forms: (1) generalized attacks analogous to those of essential epilepsy, (2) abortive (petit) attacks with short loss of consciousness and without convulsive manifestations, and (3) Bravais-jacksonian attacks. Frequent Bravais-jacksonian attacks, which remain similar for months or years, suggest the existence of a cerebral tumor affecting the pyramidal tract in the neighborhood of its origin. Conversely, Bravais-jacksonian attacks that occur less close together (months apart) and perhaps change their aspect suggest, in the absence of the syndrome of intracranial hypertension, an encephalitis and, if an intracranial hypertension exists, they suggest encephalitis or a tumor of extrapyramidal localization. But although in the presence of Bravais-jacksonian attacks that are far apart and polymorphic and are not accompanied by intracranial hypertension the possibility of a cerebral tumor can be excluded, in the presence of numerous and identical Bravais-jacksonian attacks, it is impossible to make a distinction between encephalitis and tumor, since encephalitis may also cause such a clinical picture. The generalized epileptic attacks are often without value for the localization, except that they are often the first sign of a lesion of a mute zone. In case of the abortive (petit) epileptic attacks a temporal localization should be searched for. The Bravais-jacksonian attacks, which have considerable localizing value, constitute often the alarm signal of a compression of the cerebral origins of the pyramidal bundle. The author further calls attention to the considerable prognostic value of epilepsy and particularly of Bravais-jacksonian epilepsy. A long phase of Bravais-jacksonian attacks, more or less close together, and constituting the only symptom, indicates a malignant tumor. However, it is impossible to distinguish only by clinical means an extracortical meningioma from an intraparenchymatous fibrous glioma. On the other hand, Bravais-jacksonian attacks, which are less numerous and which precede, accompany or follow the appearance of a rapidly progressing hemiplegia of the flaccid type, indicate nearly always the existence of a malignant tumor.

 \*Behavior of Denervated Adrenal Medulla. H. Hermann.—p. 1554.  
 \*Repeated Perforations of Gastroduodenal Ulcers (Description of Two Unreported Cases). J. Gosset, M. Jouanneau and J. Allamand.—p. 1556.

**Denervated Adrenal Medulla.**—For three years Hermann and his collaborators have made studies on the denervated adrenal medulla. In this report he summarizes the results which are of interest in connection with the surgical treatment of arterial hypertension or of diabetes. The investigations revealed that, after the total resection of the secretory nerves of the adrenal medulla in dogs, this gland retains an important part of its functional properties. Its microscopic structure remains normal; it does not lose the power to elaborate its specific product, which is always detected in it in considerable amounts but in smaller quantities than in the tested capsules. The epinephrine thus stored is perfectly mobilizable either by direct electrical excitation of the chromaffin tissues or by pharmacologic agents possessed of epinephrine-secreting powers. Finally the denervated gland secretes in the chloralosed animal, and under the conditions of suprarenogular anastomosis, minimal quantities

of the sympathomimetic hormone. All these observations establish the fact that the adrenals can escape from the control of the central nervous system without losing their capacity to produce and secrete epinephrine. It demonstrates its autonomic functioning and justifies the analogy between the epinephrinogenic gland and the sympathetic ganglion. The author thinks that these experimental observations deserve to be taken into consideration by those who are interested in the surgical treatment of hypertension or of diabetes by means of the denervation of the adrenals or by means of splanchnicectomy.

**Repeated Perforations of Gastroduodenal Ulcers.**

Gosset and his associates say that in view of the rarity of reports on repeated perforations they were at first under the impression that this is an exceptional accident. After describing the clinical histories of two patients with repeated perforations, whom they recently observed, the authors say that in the literature of recent years they have found sixty-four cases of repeated perforations of gastric or duodenal ulcers, disregarding of course the perforations of postoperative jejunal ulcers, which are comparatively frequent. They admit that they are unable to estimate, even approximately, the incidence of repeated perforation but point out that Pearce observed thirty-three repeated perforations among 4,183 cases of perforated ulcers (about one in 145 cases). Other authors observed two in 227 cases, one in 120, one in seventy-eight, two in ninety and four in eighty-two. These figures indicate that this complication is far from being exceptional. Discussing the pathogenesis of repeated perforations, the authors point out that it has been suggested that they are especially frequent after simple sutures. However, others have shown that this can be explained by the fact that simple suture is the method most frequently employed in the treatment of the first perforation and that on the whole the percentages correspond to those of the diverse technics employed. Regarding the seriousness of the repeated perforations the authors say that it is estimated diversely by different authors, some considering it as extremely grave and others as more benign than the first perforation. Pearce, for instance, reports a mortality as 9 per cent for the repeated perforations as compared to 27 per cent for the primary perforations. To explain the latter figures it has been suggested that the peritoneum developed a sort of local immunity after the first perforation. Discussing the treatment in cases of repeated perforations, the authors say that it does not differ from the usual treatment of perforated ulcers. The choice of the method is determined less by the repetitious character of the perforation than by the size, the location and the callosity of the orifice. The authors think that in selecting the method the surgeon should take into account especially the tenacious character of the ulceration, which is the cause of the repeated perforation. They think that in repeated perforation either gastrectomy should be done immediately or a simple method should be chosen which is least likely to interfere with a subsequent gastrectomy.

 \*Treatment of Hypogalactia by Ultraviolet Rays. M. Pelletier.—p. 314.

**Treatment of Hypogalactia by Ultraviolet Rays.**

Pelletier reports the histories of three women in whom irradiation of the breasts with ultraviolet rays proved effective against hypogalactia, after galactagogue medications had been tried without appreciable results. Following a description of the cases, the author says that this irradiation of the breasts with ultraviolet rays was first recommended in 1924. He applies gradually increasing doses every other day, the irradiations lasting from two to thirty minutes. The maximum number of irradiations is fifteen, followed by maintenance irradiations twice a week for about a month. During the irradiation, petrolatum is applied to the mamilla. The case histories indicate that the distance from the lamp to the breasts is from 60 to 70 cm. The author does not think that the results obtained with the ultraviolet irradiation are due merely to autosuggestion but assumes with some of the earlier investigators that the irradiation counteracts a disturbance in the calcium and phosphorus metabolism. Moreover, the local hyperemia probably facilitates the secretion.

\*Polyneuritis After Oral Administration of Medicaments Containing Sulfanilamide. J. Rost.—p. 92.  
Disturbances in Optic Perception in Hypoglycemia. A. Weil.—p. 98.

**Polyneuritis Following Sulfanilamide.**—Rost directs attention to undesirable secondary effects that develop following the administration of a sulfanilamide preparation that is widely used in the treatment of gonorrhea (uliron). Although the therapeutic results obtained with this preparation have on the whole been gratifying, disorders such as headaches, intestinal disturbances, vomiting and morbilliform and urticarial exanthems have been observed in about 30 per cent of the treated cases. These disorders are usually observed on the tenth day of the treatment but they disappear, after the medication is discontinued, without causing further sequels. Recently, however, polyneuritic symptoms have been observed. After citing a case that was described by Hüllstrung and Krause, Rost describes two cases of his own. Both patients developed a polyneuritis, with special involvement of the motor component, after they had been subjected to sulfanilamide therapy, under the influence of which the gonorrhea had promptly subsided. The course of the polyneuritis was slow in both cases, but by the administration of vitamin B<sub>1</sub> the improvement could be somewhat accelerated. In the discussion of the pathogenesis of the polyneuritis it is pointed out that gonorrheal disorders as such have been known to cause neuritic symptoms in rare cases. However, in the first one of the cases discussed there was evidence that the polyneuritis was caused by the medication and not by the gonorrhea. Attempts have been made to solve the problem by animal experiments, but these have produced no satisfactory results as yet. It appears probable that the dosage of the preparation plays a part. In all cases in which neuritic disturbances were observed, the total dose was far in excess of that recommended by Schreus. For this reason it may be hoped that in the future such complications may be avoided by careful watching of the dosage.

**Acute Nicotine Poisoning from Parasiticide.**—Wehrli reports the clinical history of a man aged 24 who was hospitalized with tetaniform spasms in all four extremities, abdominal spasms, nausea, headache, excessive perspiration and tachycardia. The spasms disappeared after a short time. After describing the results of the general examination, the author says that the diagnosis proved difficult at first but that poisoning was thought of. The anamnesis revealed that the patient, who was a gardener, had sprayed a parasiticide consisting of a nicotine solution. The author cites similar cases from the literature which seem to indicate that the symptomatology of this type of nicotine poisoning varies considerably. Moreover, the symptoms resemble those of other intoxications and consequently do not permit a diagnosis. The latter is made possible by an exact anamnesis and by the chemical or biologic demonstration of nicotine in the excreta. The biologic test is based on the fact that, if a nicotine solution is dropped on the tongue of a frog, the animal responds by a peculiar curving contraction of the leg onto the back. In fatal cases, all organs contain nicotine. Since parasiticides that contain nicotine are used widely in agriculture and horticulture the author advises that, if acute intoxications are observed in gardeners and persons with similar occupations, nicotine poisoning should be promptly considered.

Free Intra-Articular Bodies in Chondrosarcoma of Astragalotibial Joint. C. Leonardo.—p. 1017.

**Transfusion of Preserved Blood.**—Mingazzini gave preserved blood transfusions to twenty-six patients suffering from gastric or duodenal ulcers or from gastric cancer. The procedure was resorted to before or after a surgical intervention and in some cases transfusion was repeated. The blood had been stabilized by addition of sodium polyacetylenedioxysulfonate and preserved for from one to twelve days when it was administered to the patients. The results were similar to those which could have been obtained from transfusion with fresh pure blood. Unpleasant reactions, fever and changes in the urine did not take place. The crisis of the blood and the general condition of the patients improved in all cases. No doubt the administration of fresh pure blood is preferable whenever possible. But when not obtainable, as in many instances, blood stabilized with sodium polyacetylenedioxysulfonate and preserved for from one to twelve days can be used with safety. The technic for preparation of the blood and for transfusion is easy, the biologic and therapeutic properties of the blood do not diminish and the results are satisfactory.

Evaluation of Allergy in Tuberculosis in Adults by von Gröer's Allergometric Method. Irene Miller.—p. 1295.

**Metabolism of Creatine Bodies in Exudative Diatheses.**—Magi found, in twenty-three infants and children who had an exudative diathesis, that the elimination of creatine and creatine bodies through the urine is diminished, in relation to normal, whereas that of creatinine is increased. According to the author, the diminished elimination of creatine and creatine bodies in the presence of an exudative diathesis is due to defective development of the muscles from alterations of the cellular metabolism of proteins and nitrogen substances with a consequent imperfect assimilation of the substances by the muscular tissues. The metabolic disorders originate in congenital endocrine and neurosympathetic disturbances.

\*Lymphogranulomatosis Urethritis (Nicolas-Favre) in Women. A. Midana and Rita Leone.—p. 398.

**Lymphogranulomatous Urethritis in Women.**—Midana and Leone report eight cases of lymphogranulomatous urethritis in women. The patients had presented inguinal adenopathy in the past for periods of from one to five months. They com-

plained of a burning sensation at the urethra and had lymphogranuloma at the anus, rectum, vulva or external genitals and a positive Frei test. The urethral lesions could be seen either by simple examination or by urethroscopy. They were ulcerous, vegetative, associated ulcerous and vegetative, inflammatory or sclerotic and, in some cases, they were continuous with the external esthiomene. The disease was secondary to vulvar, anal, rectal or genital involvement in all cases. In certain cases, however, chronic lymphogranulomatous urethritis develops as the primary focus. When the disease is secondary to a primary lymphogranulomatous lesion, it originates in a propagation of the virus through the lymphatic channels with consequent disturbances of the local lymphatic circulation and damage of the tissues from direct contact with the virus.

Mastoiditis Complicated by Purpura Annularis Telangiectatica During Childhood. Margarete Wolf.—p. 114.

**Simultaneous Bronchial Asthma and Eczema.**—Casper says that all investigators agree that asthma and eczema are related and that they are symptoms of the same constitutional anomaly. The author investigated this relationship between asthma and eczema in 210 cases, giving especial attention to those in which asthma and eczema concur or alternate or in which eczema is to be found in the previous history. He describes in detail the histories of two children in both of whom there existed a hypersensitivity to milk, protein and in one case also to fats. Asthma developed for the first time when the eczema had disappeared and then the two disorders recurred alternately. In the second case there was evidence of a hereditary neuropathic component and the author suggests that neuropathy and exudative diathesis are related. He says that an allergic factor was noticeable in both cases but thinks that allergy does not explain the problem entirely. Studies on forty-two patients with chronic bronchitis and eczema revealed an asthmatic reaction in three. In all cases there were indications of a relation between eczema and bronchitis in that the bronchitic symptoms either alternated with the cutaneous manifestations or were accompanied by cutaneous exacerbations. The author further presents a report of seventy patients, thirty-nine of whom had both asthma and eczema and thirty-one only asthma. He shows that the essential factor in asthma as well as in eczema is the allergic constitution, which becomes manifest in a hypersensitivity of the organism to certain noxa, in vagotonic symptoms and in a tendency to eosinophilia. There exists a reciprocal action between eczema and asthma or bronchitis. If one of the two disorders is present in a severe

form the other one is mild or is completely absent. In this connection the author tells of a man in whom attacks of asthma and eczema alternated and who, by preventing the healing of the eczema, was able to suppress the attacks of asthma. The author thinks that, in view of the evidence of connections between asthma and eczema, the two should be considered as one and he applies the term *prurigo-asthma*. He also suggests that, since asthma with the attacks of suffocation is usually dreaded more than the eczema with its itching, it might perhaps be advisable in cases of alternate appearance of the two disorders to prevent the complete healing of the eczema.

**Tuberculosis of Bone and Joint and Pulmonary Tuberculosis.**—Frank investigated the relationship between bone and joint tuberculosis and pulmonary tuberculosis in 1,003 patients treated at the sanatorium of Heuberg. He finds that the simultaneous existence of pulmonary tuberculosis and bone and joint tuberculosis in infants and children is frequent. This is explained on the basis of the frequency and the regularity with which infection and reinfection take place at that age, as well as on the feeble resistance of young bodies. Simultaneous pulmonary involvement is equally frequent in somewhat older children; most of these exhibit advancing ulcerative pulmonary tuberculosis. Simultaneous involvement of the pulmonary tissue between the ages of 10 and 30 years is rare. The fact that most of the cases of bone and joint tuberculosis occur at this age suggests the possibility of the existence of isolated chronic tuberculosis of a single system. A spreading ulcerative pulmonary tuberculosis occurred in 2.4 per cent of all cases of joint-bone tuberculosis. The rest of the cases of pulmonary involvement presented benign forms of the disease, which is explainable by the existence of positive allergy of the body in bone and joint tuberculosis. The author does not consider the coexistence of pulmonary tuberculosis a contraindication to operative treatment of bone foci. Frequently the removal of a tuberculous focus exerts a beneficial effect on the entire organism.

**Benign Gastric Ulcers in Pernicious Anemia.**—Haring points out that the close connections between the gastric mucosa and the hemopoiesis in the bone marrow lend considerable significance to the adenomas of the mucosa. In pernicious anemia there supposedly exists a disturbance in the so-called intrinsic factor which the healthy gastric mucosa probably forms by an incretory mechanism from the vitamin B<sub>12</sub> complex. Roentgenologic studies on the benign tumors which occur during pernicious anemia revealed to the author considerable secretory activity, and histologic studies on the tumors disclosed adenomas that were filled with colloid. He thinks that histologically they resemble the adenomas of the thyroid which occur in exophthalmic goiter or myxedema and suggests that the adenomas of the gastric mucosa might be related to the incretory activity. Surprising is the content in Hance-

mann's bodies, the nature and the significance of which are still unknown. The author realizes that further investigations on true polyps of the mucosa in pernicious anemia will be necessary to clarify the relation between the two disorders and he hopes that this report will stimulate such studies. He suggests that all patients with pernicious anemia and those with funicular myelitis traceable to pernicious anemia be subjected to roentgenologic examination of the stomach to detect possible polyps of the mucosa. Moreover, if polyps are detected by surgeons or roentgenologists the patient under observation should be subjected to internal examinations in order to detect possible relations to pernicious anemia or other hyperchromic anemias.

**Experiences with Cycloscope of Samuels.**—The original and new opinions expressed by Samuels on the menstrual cycle, ovulation, the periodic fertility and the early diagnosis of pregnancy (see abstracts in *THE JOURNAL*, February 26, page 696, and April 9, page 1241) induced Imbach of the women's clinic in Zurich to investigate Samuels' claims. Imbach made his studies with the cycloscope recommended by Samuels. In a considerable number of women between 21 and 45 years of age and in one man, the reduction time was determined daily over a period of seventy-five days. As recommended by Samuels, curves were plotted of the reduction time in order to obtain so-called cyclograms. It was found that the technic is not as simple as had been suggested by Samuels and that there are many sources of error; for instance, it was found that the reduction time differs after the hands have been bathed in warm or cold water. Moreover, there is a difference whether a thick or a thin fold of skin is clamped off. The results obtained by the author do not tally with those obtained by Samuels. In not a single one of the normal persons subjected to the cycloscope test did he obtain curves that approximated those of Samuels. He reaches the conclusion that Samuels' spectroscopic method does not reveal typical increases and decreases in the reduction time of the oxyhemoglobin within the monthly cycle and that the far-reaching and revolutionizing conclusions arrived at by Samuels lack a foundation that stands up under investigations.

**Hypertonic Sugar Solutions Intrapleurally in Pleurisy and Empyema.**—Bauer says that the conservative treatment of exudative pleurisy and the surgical treatment of empyema do not always produce satisfactory results and that a survey over the various methods of irrigation and instillation which have been recommended to accelerate cure and to avoid the formation of indurations and callosities reveals that none of the therapeutic methods satisfy completely. The results which Lexer obtained with the application of sugar to slowly healing wounds induced the author to resort to the intrapleural injection of hypertonic solutions of sugar in six cases of exudative pleurisy. It was thought that, by increasing the osmotic pressure in the exudate, a profuse fluid secretion could be obtained from the pleural endothelium. This was to prevent the formation of indurations or perhaps dissolve existing ones. It seemed possible also that the juxta-pleural parts of the lung could be favorably influenced by withdrawing water from them. It was assumed that, following this discharge of fluid, a better blood perfusion would result. However, no adequate action could be obtained in this manner, because the greatly impaired pleura likewise absorbs sugar rapidly, so that there is no pro-

longed osmotic action. To be sure, the author thinks that Spengler's method of treating spontaneous pneumothorax by means of hypertonic solution of dextrose is to be recommended, because the hypertonic sugar solution noticeably stimulates the resorptive action of the pleura. The observation that a mild osmotic stimulus accelerates the resorption of exudates suggests that, in the case of many of the substances that have been recommended for irrigation or instillation, not the particular composition but the stimulus on the pleura promoted the resorption.

**Action Mechanism of Insulin.**—Brühl says that it is now generally conceded that insulin increases the motility and the secretory action of the stomach and that the last named action has led to the use of insulin in gastric diagnosis. In experiments on a large material, Kalk and Meyer gained the impression that in the action of insulin on the stomach the liver is in some manner involved. For this reason Brühl decided to investigate the action of insulin on the stomach of patients with hepatic diseases. He found that in severe disorders of the liver the latent period, that is, the time which elapses between the injection of insulin and the onset of the increased gastric secretion, is prolonged. He thinks that changes in the course of the blood sugar fluctuations are of causal significance in this delay: there is a flattening of the blood sugar curve, and the hypoglycemic values are reached later than is normally the case. Since the increase in gastric secretion that is observed after the administration of insulin is a result of the vagal irritation produced by the hypoglycemia, a retardation of the one must result in a retardation of the other. On the basis of blood sugar curves determined after administration of insulin in healthy persons and in patients with hepatic disease, the action mechanism of insulin is discussed and it is shown that the liver has an important part in the blood sugar fluctuations. It appears that the insulin blood sugar curve can be utilized for the detection of functional disturbances of the liver. However, the determination of the latent period of the gastric effect of insulin by means of the fractionated withdrawal of the gastric contents has sufficient reliability as a diagnostic aid only in the presence of severe hepatic impairment.

What Conditions in Microscopic Structure of Chromosomes Are Responsible for Recessivity of a Gene. Gertraud Hasse-Bessell.—p. 258.

**Heredity of Allergic Diseases.**—In this discussion of the heredity of allergic diseases, Sachsse gives particular attention to hay fever. He reports studies on the families of thirty-eight patients with hay fever. The reports of some authorities on allergic diseases induced him to inquire in his hay fever patients and their families for disorders such as conjunctivitis during the spring months, asthma after contact with certain odors and substances, gastrointestinal disturbances after the ingestion of certain foods, and disorders such as urticaria, Quincke's edema, eczema, cholelithiasis, nephrolithiasis, gout, sciatica, rheumatism, migraine, exophthalmic goiter and gastric ulcer. On the basis of his studies he answers the question regarding the hereditary transmission of an allergic predisposition in the affirmative. However, environmental factors seem

to play an important part in the elicitation of an allergic symptom, so that it is possible that in one generation the allergic disposition is not so evident and that in an otherwise evidently dominant transmission it can be found that one generation has been missed. The author gained the impression that for a "strong" allergic predisposition it is necessary that at least two genes be present which carry an allergic tendency. Hay fever seems to become manifest only if at least two such genes concur, that is if either a "strong" predisposition is transmitted from one parent or a "weak" monomeric one from both parents. The author thinks that if two or more factors play a part it is understandable why the family anamnesis is not always so clear as is the case of monomeric dominant transmission. In this connection the author cites observers who assume a recessive transmission. In his own material the recessive transmission was contraindicated also by the fact that there were practically no marriages in relationship in the hay fever families investigated by him. He points out further that Hanhart's observation that in case of allergy in both parents not three fourths but only two thirds of the children are allergic might indicate a dimerous dominant transmission. He concludes that a complete and exact explanation of the mode of hereditary transmission requires further serial statistical studies, and especially investigations on twins.

**Therapy of Encephalitis.**—Van der Scheer and Zijlstra direct attention to the use of methenamine in the treatment of encephalitis and of related neurotropic infections. After reviewing the literature on this treatment, they report the results obtained with it in more than 200 cases at the clinic for psychiatry and neurology in Groningen. A tabular report indicates that the material included patients with various forms of encephalitis, disseminated and transverse myelitis, postencephalitic parkinsonism, chorea minor, herpes zoster, radiculitis, Landry's paralysis, polyneuritis, poliomyelitis and others. On the basis of their experiences the authors recommend this treatment. They administer the methenamine in the form of a 40 per cent solution by means of intravenous injections. The individual dose is 10 cc., which usually is given every other day. The total dose is from 100 to 200 cc.

- Diagnosis of Extrapleural Abscess. H.-G. Skarby.—p. 259.

**Roentgen Diagnosis of Tuberculous Spondylitis.**—Westermark and Forssman demonstrate that from the roentgenologic point of view tuberculous spondylitis can be divided into a focal and a diffuse osteitis. The focal osteitis is more common in adults and the diffuse osteitis is more frequent in children. In focal spondylitis two different types are to be differentiated. One type is surrounded during the early stage by a circumscribed otosclerosis and by periosteal deposits; the other type is characterized by a rounded or irregular sequestrum and a rarefied border zone. Both types of focal spondylitis are localized most frequently in the anterior lateral border of the vertebral body. In focal spondylitis roentgenologic diagnosis is possible at an early stage, whereas in diffuse spondylitis the roentgenologic discovery is usually rather late.

- Widmark's Micromethod Applied in Determination of Ethyl Ether in Blood. O. Dybing.—p. 1105.

**Progressive Muscular Dystrophy in Family.**—Wagner examined fourteen of the affected members of the roving family in question, spread over the western part of Norway. There was paralysis without rigidity; of the patients with advanced atrophy accompanied by suspended or weakened tendon reflexes only three or four were so disabled that they had to be quiet. Of the thirty-five marriages that he traced in the family twelve, or about 35 per cent, were intermarriages, which he explains as due to social isolation. He concludes that a partially dominant factor is present, the affected persons being heterozygote with reference to the factor. The fact that three women, although undoubted bearers, have escaped the disorder may be accidental but may also mean that women are less liable to it than men. While the probability is not strong, he says, that nervous disorders are correlated with the muscular dystrophy, he found deafmutism in two cases in this family, epilepsy in one, manic-depressive insanity in one, mental unbalance in two, "queerness" in one and schizophrenia in one. There was also a criminal trend.

**Ascorbic Acid in Pregnancy, Puerperium and New-born.**—Elmby and Becker-Christensen made 4,000 determinations of the ascorbic acid in the blood, urine and milk in 200 women through the last five months of pregnancy and during birth and the puerperium, and determined the ascorbic acid in the umbilical blood and blood from the ear of the newborn. There was agreement between the ingested ascorbic acid and the spontaneous ascorbic acid concentration in the blood and milk. The titer of the serum ascorbic acid fell during pregnancy, whether the diet was deficient or rich in vitamin C, but not to excessively low values in the women whose diet was rich in vitamin C. The titer of the ascorbic acid in the serum in the newborn child depends on the concentration of the serum ascorbic acid in the mother and falls during the first ten days of life. The ascorbic acid concentration in the milk depends on the titer of the ascorbic acid in the mother's serum. By the additional administration of 100 mg. of ascorbic acid daily in the first ten days of the puerperium the ascorbic acid in the mother's serum and milk can be raised from subnormal to normal value. The titer of ascorbic acid in the child's serum follows that of the milk and therefore depends on the mother's diet.

## THE ROLE OF POTASSIUM IN FAMILIAL PERIODIC PARALYSIS

ROBERT H. PUDENZ, M.D.

JOHN F. MCINTOSH, M.D.

AND

DONALD McEACHERN, M.D.

MONTREAL

This rare but fascinating disease was first described by Cavaré<sup>1</sup> in 1853 and later in 1874 by Hartwig,<sup>2</sup> who named it intermittent spinal paralysis. It is characterized by recurrent attacks of flaccid paralysis affecting mainly the muscles of the trunk and limbs, during which the deep reflexes disappear and the muscles become inexcitable to electrical stimulation. Attacks usually come on during sleep without previous warning; they last from a few hours to three or four days. In the interval muscular power is normal and the patient is entirely well. Attacks first make their appearance during childhood or adolescence and become less frequent or disappear in later life. Males are twice as often affected as females. Sporadic cases have been reported, but the condition is usually hereditary; Holtzapple<sup>3</sup> has described seventeen cases in four generations of the same sibship. Many theories have been advanced to explain these weird and crippling seizures.

The most comprehensive study of the disease has been made by Shinosaki,<sup>4</sup> who published his observations in twenty-four cases. Among the more important observations were the frequent (62 per cent) association of the disease with thyroid struma and the tendency for attacks to occur after administration of thyroid, epinephrine or diets high in carbohydrate. Hyperglycemia was often observed during the early stages of spontaneous attacks, and albuminuria was present during attacks in 73 per cent of the cases. Shinosaki carried out many ingenious experiments and concluded that the disease was a polyglandular syndrome in which the thyroid played an important part.

Our interest in the condition, and especially in the role of potassium, was aroused by the work of Herrington.<sup>5</sup> He reported the cases of two brothers who

averted paralysis by the ingestion of potassium citrate when prodromal symptoms appeared but he offered no explanation of the mechanism and carried out no metabolic studies. In 1901 Singer and Goodbody<sup>6</sup> administered potassium acetate to a patient with this disease in an attempt to promote diuresis and noted that attacks of paralysis became less frequent and severe. Holtzapple<sup>3</sup> had similar success with potassium bromide but attributed it to a sedative action of the bromide. Moreover, Biemond and Daniels<sup>7</sup> found a serum potassium value of 13.38 mg. per hundred cubic centimeters in a mild spontaneous attack and a value of 17.87 mg. during an interval but did not appreciate the significance of their results.

Since the commencement of our work, Aitken, Allott, Castleden and Walker<sup>8</sup> have reported their careful study of a patient with this disease. More recently Ferrebee, Atchley and Loeb,<sup>9</sup> Allott and McArdle<sup>10</sup> and Gammon<sup>11</sup> have published their observations. In agreement with their results we have found that attacks are associated with a marked fall of serum potassium and that administration of adequate amounts of potassium salts brings about rapid recovery.

We have produced attacks by administration of dextrose, epinephrine and ephedrine and have brought about recovery by injection of choline chloride carbamate (doryl) and acetyl- $\beta$ -methylcholine chloride (mecholy). Studies of electrolyte balance and the results of intravenous and intra-arterial injections of potassium chloride have thrown light on the mechanism of the attacks. A defect of creatine metabolism has also been observed, as noted in our preliminary report.<sup>12</sup>

L. H., a youth aged 18, has had recurrent attacks of paralysis involving the muscles of the trunk and extremities, and to a lesser extent the muscles of mastication and expression, since the age of 11. Similar attacks have occurred in the father, one brother and one sister.

The attacks almost invariably begin during sleep and last from twenty-four to forty-eight hours. He knows of no precipitating factors. Between the attacks he is active and feels perfectly well. Examination during the interval elicits no abnormality. Of late, attacks have been occurring several times each month.

The weakness begins in the muscle groups of the back and hips and within one or two hours extends to involve the neck,

the shoulder girdle and the upper and lower extremities. Weakness is occasionally hemiplegic in distribution at the onset but soon spreads to involve the opposite side. During severe attacks the patient is helpless and unable to make the slightest movement of the trunk or extremities. There is no disturbance of sensation.

Throughout the attacks he is depressed, irritable and uncommunicative and complains of headache, anorexia and nausea.

Chart 1.—Attack following adrenal cortex extract. The cerebrospinal fluid potassium did not alter with changes of serum potassium.

The pupils dilate widely and he is hypersensitive to light. The heart rate often drops to 40 beats a minute, and a systolic murmur develops at the apex. The skin is cool and the extremities are apt to be more moist than usual. The limbs are flaccid and the deep reflexes disappear while the superficial reflexes remain. During complete paralysis there is no muscular response to faradic or galvanic stimulation of nerve or muscle. Recovery of electrical reactions parallels the return to voluntary muscular power.

#### METHOD OF STUDY<sup>13</sup>

The patient was kept under observation for six months. Studies were made of eighteen separate attacks, of which eight were spontaneous and ten were induced. His intake of food and fluids and the collection of urine and stools were rigidly supervised. He received two standard diets which were alternated every three days. Expressed in grams, the two diets consisted of (a) protein 95, fat 68, carbohydrate 329 and potassium 3.73 and (b) protein 97, fat 110, carbohydrate 321 and potassium 3.93.

The potassium was checked by analysis of a duplicate diet. The sodium content was arrived at by calculation and the weighing of additional sodium chloride consumed. There was some variation of fluid intake as the result principally of the anorexia induced by the attacks, but at no time during the course of the experiment did the patient fail to consume the outlined diet. The urine was analyzed for potassium, sodium and chloride and the feces were analyzed for potassium. The urine was collected in twenty-four hour periods,

save during the attacks when determinations were made in six or twelve hour periods. Stools were analyzed in periods representing three days of excretion. Standard methods were used for the chemical determinations. Potassium was estimated by the method of Kramer and Tisdall.<sup>14</sup>

#### METABOLIC STUDIES

**Potassium.**—Blood Serum and Corpuscles: There was invariably a marked fall of serum potassium during the paralytic phase both in induced and in spontaneous attacks (charts 1 and 2). These values ranged from 7.7 to 12.4 mg. per hundred cubic centimeters during complete paralysis. In one induced attack a value as high as 17.4 mg. was found during almost complete paralysis. The critical level in our patient was therefore variable. With improvement of muscular power the serum potassium rose again toward normal. There was also considerable variation of serum potassium during the interval phase. It ranged from 17.5 to 30 mg. per hundred cubic centimeters, although it usually lay between 22 and 25 mg. In the case studied by Aitkin and his associates,<sup>8</sup> onset of paralysis occurred when the serum potassium fell to 12 mg. per hundred cubic centimeters. A patient studied by Allott and McArdle<sup>10</sup> showed weakness whenever the level fell below 16 mg. per hundred cubic centimeters. Determinations of corpuscular potassium were made during two attacks. The serum was separated immediately after the blood samples were drawn. We are not able to interpret the variations of potassium in the blood cells (charts 1 and 2).

**Intake and Output:** Despite a constant intake of potassium, the excretion varied quite markedly from

Chart 2.—Attack induced by epinephrine. No improvement after injection of 1.0 mg. of prostigmine intramuscularly. Note bradycardia and lowering of plasma carbon dioxide capacity during attack. Recovery after potassium chloride (5 Gm.) orally.

day to day. However, at no time was there any evidence of a positive or negative potassium balance over a representative period. During attacks there was a marked decrease in the excretion of potassium in the urine (chart 3), especially in the six hour specimens representing the phases of most marked paralysis. This was independent of urinary volume. A compensatory

13. Miss Constance Lambertus supervised the nursing and Mrs. Ruth Salter and Miss Doris Brophy made the chemical determinations.

14. Kramer, B., and Tisdall, F. F.: Clinical Method for Quantitative Determination of Potassium in Small Amounts of Serum, *J. Biol. Chem.* 46: 339 (April) 1921.

increase of output followed attacks. The first two attacks pictured in chart 3 were terminated by administration of potassium. The potassium content of the feces was variable but the total amount excreted was insignificant when compared to the urinary amount.

Cerebrospinal Fluid: During one attack the potassium content of the cerebrospinal fluid was determined

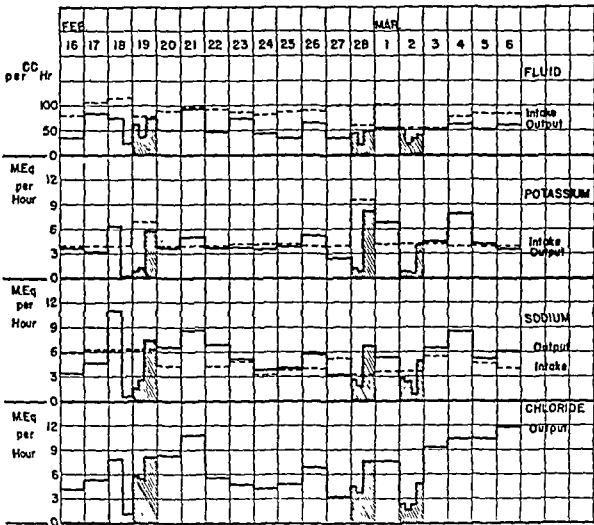

Chart 3.—Daily intake and urinary output of fluid, potassium, sodium and chlorides. The output of potassium, and to a lesser extent of sodium, is decreased on the days of the attacks. The latter are represented by the shaded areas. No diuresis of potassium preceded attacks.

on four different samples, representing stages from paralysis to almost complete recovery (chart 1). The values obtained varied from 10.3 to 12 mg. per hundred cubic centimeters, all of which were within the normal range of from 10 to 14 mg. There was no decrease corresponding to the lowering of serum potassium. The determinations covered a period of twelve hours, which seemed ample time for a change to become evident if

Range of Level of Inorganic Phosphate, Calcium and Sodium in Blood Serum		
	During Intervals, Mg. per 100 Cc.	During Attacks, Mg. per 100 Cc.
Serum inorganic phosphate.....	3.62- 4.75	2.74- 4.75
Serum calcium.....	10.4 - 11.8	10.1 - 11.4
Serum sodium.....	326.0 - 386.0	335.0 - 355.0

it was going to occur. A specimen of cerebrospinal fluid obtained during the interval phase contained 11.6 mg. of potassium per hundred cubic centimeters.

Other Electrolytes.—The urinary excretion of both sodium and chloride (chart 3) showed a slight decrease during the paralytic phase, followed by a compensatory increase during and after recovery. In the blood, the level of other important electrolytes was normal or without constant change during attacks. The range of numerous determinations is shown in the accompanying table.

Plasma Carbon Dioxide Capacity.—The carbon dioxide combining power of plasma was reduced moderately but consistently during attacks. Values obtained during two uninduced attacks were 50.4 and 52.9 volumes per cent. In one attack, induced by epinephrine, six values were obtained which varied from 43.5 to 53.7

volumes per cent. All values obtained during the interval phase have been above 64.4 volumes per cent.

Creatine and Creatinine.—Studies of creatine and creatinine in the blood and urine both during the attacks and in the interval phase have shown two definite abnormalities: (a) excretion of creatine in amounts up to 0.65 Gm. in twenty-four hours and (b) a highly variable daily excretion of creatinine, the range being from 0.78 to 2.13 Gm. in twenty-four hours. These abnormalities bore no constant relationship to attacks (chart 4). The blood creatine and creatinine have always been within normal limits (chart 5).

Sugar.—Numerous determinations of plasma dextrose have fallen within a normal range or within the range of expectation following administration of dextrose, insulin and epinephrine. When attacks have been induced by those substances the fall of serum potassium has not been related to hyperglycemia or hypoglycemia (charts 2 and 6).

Choline Esterase.—Determinations of acetylcholine esterase in defibrinated blood and in serum were made by the method of Ammon.<sup>15</sup> The activity of this enzyme was not abnormal either during or between attacks. The mean values for five determinations on serum made during attacks and five made during intervals were 50.4 cubic millimeters of carbon dioxide and 48.4 cubic millimeters of carbon dioxide respectively. These results are well within the range found for a large number of normal persons.

PRODUCTION OF ATTACKS

Spontaneous attacks were infrequent and attempts were made to induce them. We enjoyed fair but not invariable success with epinephrine, ephedrine, large doses of dextrose or dextrose combined with either insulin or epinephrine. The success of these measures must depend on the natural cycle of the disease at the

Chart 4.—Persistent creatinuria and marked daily variation in urinary creatinine. Shaded areas represent days of attacks.

time they are applied. In addition, frequent attempts to induce attacks seemed to lead to a refractory state; thus, four times in one week the administration of 200 Gm. of dextrose failed to produce an attack. Repeated use of the other substances led to similar failures.

Dextrose was given orally in amounts of from 200 to 250 Gm. at from 10 to 11 p. m. or in the early morn-

15. Ammon, R.: Die fermentative Spaltung des Acetylcholins, Arch. f. d. ges. Physiol. 233: 486, 1933.

ing. If paralysis occurred it developed within three or four hours. Sometimes paralysis was incomplete. Twice, when no paralysis developed, administration of 1 cc. of epinephrine at hourly intervals led to paralysis within two hours of the first injection. On one occasion the combined use of insulin and dextrose led to a typical attack.

Epinephrine was given subcutaneously in 1 cc. (1 mg.) doses at hourly intervals. The sum total on any one occasion was 5 cc. If paralysis was forthcoming it tended to appear within two or three hours of the first injection. Ephedrine sulfate  $1\frac{1}{2}$  grains (0.1 Gm.) was given each hour by mouth. The results were similar to those obtained with epinephrine. On one occasion paralysis developed within one hour of the first dose.

Adrenal cortex extract was tried on two occasions because of its ability to decrease sodium and increase potassium excretion. The first time 50 dog units of Connaught Laboratory extract was given. The second time 80 units was given intravenously, as described by Thorn and his associates.<sup>16</sup> Each time paralysis developed on the day following the test. These experiments were inconclusive in that (a) chemical studies failed to demonstrate any increase in urinary potassium following administration of adrenal cortex extract, (b) dextrose was also given prior to one of the attacks.

The lowering of the alkali reserve during attacks led to an attempt to induce paralysis by acidosis. Seven hundred grains (45 Gm.) of ammonium chloride was administered orally over a period of four days. The carbon dioxide combining power fell from its initial level of 69 volumes per cent to 35.9 volumes per cent but the serum potassium remained quite stable, at no

Chart 5.—Attack following epinephrine. Plasma creatine and creatinine remained stable. Injection of potassium chloride into brachial artery did not cause recovery in injected limb.

time falling below 17.9 mg. per hundred cubic centimeters. Slight weakness appeared in the back and the legs on the fourth day but no paralysis ensued.

No success followed an attempt to "wash out" potassium by large amounts of physiologic solution of sodium chloride intravenously, nor did lowering of the body temperature from 99.2 to 96.4 F. in a cold bath or taking severe and prolonged exercise lead to attacks.

16. Thorn, G. W.; Garbutt, H. R.; Hitchcock, F. A., and Hartman, F. A.: Effect of Cortin on Renal Excretion of Sodium, Potassium, Chloride, Inorganic Phosphorus and Total Nitrogen in Normal Subjects and in Patients with Addison's Disease, *Endocrinology* 21: 213 (March) 1937.

#### ALLEVIATION OF PARALYSIS

**Potassium.**—Administration of potassium has invariably resulted in prompt disappearance of the paralysis. We have used potassium chloride most often, but the citrate is equally effective, although somewhat larger doses are necessary to provide an equivalent amount of potassium.

Chart 6.—Attack after dextrose and insulin. Lowering of serum potassium was not associated with hypoglycemia. Potassium chloride 1 Gm. intravenously caused partial recovery without elevation of serum potassium.

Potassium chloride, from 5 to 10 Gm. in watery solution by mouth, brought about return of movement within thirty minutes to one hour and the ability to walk unaided within two hours. Recovery was associated with a progressive rise of serum potassium (charts 1 and 2). Intravenous injection of potassium chloride caused much more rapid and dramatic recovery, the only disadvantage being intense burning pain along the course of the vessel even when the salt was injected in a concentration as low as 0.5 per cent. We usually injected 50 cc. of 2 per cent solution (1 Gm. of potassium chloride) during the course of ten minutes or less and did not exceed this amount. Severe thirst and cardiac extrasystoles sometimes occurred, but they disappeared when the injection was complete. Movement began to return in the limbs from four to eight minutes after the injection was begun, and the patient was able to stand within thirty minutes.

In his most severe attack the patient was almost unconscious and artificial respiration was necessary. Even the last rites of the church had been administered. Twenty minutes after the intravenous injection of 1 Gm. of potassium chloride the patient was sitting up and chatting. This amount was insufficient for complete recovery, however, and a further dose of the salt was given by mouth.

Since his discharge from the hospital four months ago, the patient has returned to full activity and has remained free from attacks. This has been achieved by the ingestion of 5 Gm. of potassium chloride each night as a prophylactic measure. Attacks had been occurring almost weekly prior to admission.

**Choline Esters.**—Acetyl- $\beta$ -methylcholine chloride (mecholyl) 25 mg., was injected intra-arterially on two occasions. Movement became perceptible in the limbs within eight minutes and progressed to complete recovery. Choline chloride carbamate (doryl) 0.25 mg. was injected during two attacks, once intravenously and

once intra-arterially. Generalized movement commenced in four minutes on each occasion and progressed to complete recovery. Complete recovery thus occurred within two or three hours in all four instances without administration of potassium, while the serum potassium rose to the normal level as muscular power improved (chart 7).

In all experiments atropine, from  $\frac{1}{15}$  to  $\frac{1}{50}$  grain (0.0009 to 0.0013 Gm.), was given prior to the choline esters to reduce unpleasant side effects. Atropine itself had no effect on the attacks save for the fact that it caused the heart rate to increase from about 40 to 120 a minute, showing that the bradycardia was of vagal origin.

**Other Drugs.**—Prostigmine methylsulfate was administered intramuscularly during four attacks..

On one occasion after 0.5 mg. there was steady improvement for an hour and a half and the patient could walk. The effect wore off after three hours and paralysis returned. A temporary but less marked improvement occurred another time following 1 mg. On the third occasion 1.5 mg. of prostigmine was without effect. In one attack the drug was given after potassium had been administered and recovery was much more rapid than with potassium alone. The drug seemed capable of potentiating the recovery mechanism but obviously did not supply the mechanism itself.

Ergotamine tartrate had no effect on the paralysis.

#### MECHANISM OF ATTACKS AND SITE OF ACTION OF POTASSIUM

The foregoing results show that paralysis is associated with a redistribution of potassium between the blood and the body tissues. It was at first suspected

Chart 7.—A, attack induced by ephedrine and terminated by intra-arterial injection of mecholyl. B, attack induced by dextrose and ephedrine. Recovery followed 0.25 mg. of doryl intravenously. (Note the rise in serum potassium during recovery following injection of these choline esters.)

that the attacks developed because of abnormal loss of potassium from the body—a kind of potassium debt. This was disproved by balance studies. No undue loss of potassium preceded the attacks, and during the attacks excretion of potassium was greatly diminished. Indeed spontaneous recovery had often occurred without dietary or other sources of potassium, and this argued against depletion of the body's potassium stores.

During attacks the serum yielded its potassium to supply the demands of the tissues. On several occasions 1 Gm. of potassium chloride was given intravenously, improvement was rapid and the patient was walking within thirty minutes. During such partial recovery the serum potassium remained low, however, indicating that the injected potassium was leaving the serum and going elsewhere (charts 6 and 8).

Where then did the lack of potassium operate to produce paralysis and where did injected potassium remedy

Chart 8.—Attack induced by dextrose and epinephrine. Potassium chloride injected into the right brachial vein. Note recovery of left arm despite arterial occlusion by tourniquet. The injected potassium rapidly disappeared from the blood serum. Serum potassium rose later during more complete recovery.

the defect? The distribution of paralysis and the loss of electrical excitability of the muscles pointed to a fault in the muscles themselves. On one occasion 20 cc. of potassium chloride in 0.5 per cent solution was injected into the left brachial artery while the venous return was obstructed for eight minutes by a blood pressure cuff inflated to 60 mm. of mercury to confine the potassium to the limb. Severe pain and intense vasoconstriction followed by flushing showed that the potassium had spread throughout the limb, but there was no recovery of power in the muscles. This amount of potassium chloride (0.1 Gm.) was theoretically sufficient to cause some local recovery, since as little as 0.5 Gm. had caused general improvement when injected intravenously in previous attacks. A negative result was obtained another time when 0.05 Gm. of potassium chloride was injected into the femoral artery.

These results suggested that the curative action of potassium was central or that some other substance was formed in the viscera by the action of potassium and thence carried to the muscles to restore their contractility. This led to the trial of certain choline esters as previously described. Intra-arterial injection of these substances caused no local recovery of power in the injected limb but when they entered the general circulation prompt recovery occurred throughout the body. We have no explanation at present for this action of the choline esters unless perhaps they stimulate some organ or tissue to release stored potassium.

From the following experiment (chart 8), which has been repeated three times with similar result, we are forced to conclude that the defect responsible for paralysis lies in the central nervous system: The arterial supply to one arm was occluded for from thirteen to seventeen minutes by a blood pressure cuff inflated to 200 mm. of mercury, while potassium chloride (50 cc. of a 2 per cent solution) was injected rapidly into the vein of the opposite arm. Movement began to return

in about five minutes in all limbs and recovery was as rapid in the still occluded limb as in the others. In other words, recovery occurred in a limb which was completely isolated from the rest of the body as regards humoral channels. These observations indicate that the defect is neurogenic. We have no explanation for the loss of direct electrical excitability of the muscles on this basis.

## COMMENT

In the patient with familial periodic paralysis the relationship of paralysis to reduction of serum potassium is clear but there is no indication of why the change comes about. It seems likely that potassium leaves the blood stream to supply a demand of the tissues. Excess of potassium in nerve or muscle is probably not responsible for paralysis, since administration of potassium is remedial. Nor is the low level of serum potassium the essential factor, since considerable partial recovery may occur after administration of potassium while the serum level as yet shows no elevation. When potassium is administered it may restore the excitability of nerve or muscle or it may act as intermediary for the production of some other substance which is capable of doing so. Our experiments indicate that the remedial effect is on the central nervous system and not on the muscle directly. Spontaneous recovery or that following administration of choline esters suggests that some organ or tissue is capable of releasing sufficient potassium to rectify the needs of the inexcitable nerve or muscle and also to raise the serum level to normal.

The experiments of Allott and McArdle<sup>10</sup> indicate that in addition to undue lability of serum potassium some abnormality of the neuromuscular mechanism is present in this disease. They have succeeded in reducing the serum potassium to 10.5 mg. per hundred cubic centimeters in normal persons and have observed a level as low as 7.6 mg. in one person. In no instance was there paralysis. There is support for this in the abnormality of creatine metabolism described by Ferrebee, Atchley and Loeb<sup>9</sup> and by us. In our case there was persistent creatinuria even between attacks, and creatinine excretion was variable. Allott and McArdle found alterations of phosphorus metabolism paralleling those of potassium, and Milhorat<sup>17</sup> noted a negative phosphorus balance following attacks.

The fact that family periodic paralysis has been found to be an inborn error of metabolism should stimulate work on other hereditary diseases of the neuromuscular system which are at present looked on with such pessimism. It is of interest that the distribution of affected muscles in this disease is the opposite of that in myasthenia gravis and is similar to that seen in the myopathies. Biemond and Daniels<sup>7</sup> observed that in some patients with familial periodic paralysis an atrophy of the muscles most affected by paralysis developed in later life.

It is possible too that the condition may exist in minor forms which do not lead to complete paralysis. Shinosaki<sup>4</sup> was of the opinion that attacks of sudden weakness in the legs occurring in some patients with exophthalmic goiter (so-called Basedow's paraplegia) were minor examples of periodic paralysis. In view of the effect of insulin on serum potassium it would also seem advisable to test this possible mechanism in the

rare monoplegias and other neurologic phenomena which do not respond to dextrose in cases of insulin shock. With the cooperation of Dr. T. E. Dancy we have determined the serum potassium in four patients receiving shock treatment for schizophrenia. Blood was taken before administration of insulin and again after from one and one-half to two hours of hypoglycemic coma. There was no significant change in serum potassium. These were patients, however, who recovered rapidly after the administration of dextrose and there were no persisting neurologic defects.

It is not possible to say whether the abnormality of potassium metabolism is peculiar to this disease or whether it is an exaggeration of a normal mechanism. Sodium metabolism appears to be unaffected and the defect is therefore unlike that of adrenal cortical activity.

The age incidence of the disease, its periodic character and its relation to thyroid activity all suggest an endocrine upset. At present, however, no gland or hormone is known to have so direct a relationship to potassium metabolism, and the primary cause of the disease must await further investigation.

## SUMMARY

1. In a classic case of familial periodic paralysis, attacks were associated with a marked fall of serum potassium. During recovery the serum potassium rose to normal.

2. Administration of potassium caused rapid disappearance of paralysis. Acetyl- $\beta$ -methylcholine chloride (mecholy) and choline chloride carbamate (doryl) also brought about recovery, although no potassium was administered. Prophylactic doses of potassium have prevented the occurrence of attacks.

3. Attacks were induced by the ingestion of large amounts of dextrose, with or without insulin, and by the administration of epinephrine or ephedrine.

4. Paralysis was not associated with a loss of potassium from the body. There was, however, a redistribution in which potassium was drained from the serum presumably to meet the needs of the tissues. No significant change occurred in the concentration of sodium or other important electrolytes in the blood.

5. Persistent creatinuria was present during attacks and in the intervals. Creatinine excretion in the urine was highly variable.

6. Experiments have indicated that the chemical defect responsible for paralysis lies in the central nervous system and not in the muscles.

7. Familial periodic paralysis is an inborn error of metabolism.

---

**Hobbies.**—A profession cannot occupy all of one's time—or it ought not to—lest one become lopsided. Hobbies fill a gap in the lives of those who are most well rounded and promise equal satisfactions for less complete lives. . . . If you can grow, if you can relax, if you can be stimulated and refreshed by your hobby-tonic, you probably have found the right one. If you have not yet found it, begin thinking about it now, remembering meanwhile that Omnipotence of Thought isn't as efficacious as it once was, and that the surest way to develop an interest in a hobby is not by thinking about it but by doing something about it. You may be surprised how far it will take you. Hobbies cannot be developed on command. They develop by stages and are truly an expression of your very self.—Anderson, Camilla M.: *Emotional Hygiene*, Philadelphia, J. B. Lippincott Company, 1937.

STUDIES ON THE MECHANISM OF  
THE ACTION OF SULFANILAMIDEI. THE BEARING OF THE CHARACTER OF  
THE LESION ON THE EFFECTIVENESS  
OF THE DRUG

JOHN S. LOCKWOOD, M.D.

ALVIN F. COBURN, M.D.

AND

HERBERT E. STOKINGER, Ph.D.

NEW YORK

The original observations of Domagk<sup>1</sup> on experimental mouse peritonitis and the clinical observations reported by Schreus<sup>2</sup> using prontosil (the disodium salt of 4-sulfamido-phenyl-2'-azo-7'-acetylamino-1'-hydroxynaphthalene-3',6' disulfonic acid) in the treatment of erysipelas led to the present investigations in April 1935. We have been interested, first, in evaluating the effectiveness and the limitations of this chemotherapeutic agent and its derivatives; second, in determining its mode of action, and, third, in throwing light on the biology of the hemolytic streptococcus. During the course of this study an increasing number of clinical reports have appeared; the effectiveness of sulfanilamide in certain infections needs no confirmation. The present report concerns itself primarily with an attempt to determine the mode of action on a number of bacterial infections encountered in a general hospital.

The published reports on the mode of action of sulfanilamide have in most instances dealt with observations in vitro or with a single type of experimental infection, peritonitis in the mouse,<sup>3</sup> and empyema in the rabbit.<sup>4</sup> Recently Osgood has added observations on culture of bone marrow.<sup>5</sup> It seemed to us that a study of the drug's effect on various types of hemolytic streptococcus diseases as they occur in man might lead to a hypothesis which could then be subjected to experimental tests. In this report the observations are chiefly clinical. Further experiments on the action of sulfanilamide in vitro will be reported shortly by one of us (J. S. L.).

## GENERAL PROCEDURE

The present observations are drawn from the first 250 patients (1936 and 1937) treated with sulfanilamide in the various services of the Presbyterian Hospital-Columbia University Medical Center and Willard Parker Hospital. Each infection was identified bacteriologically. Each patient was seen daily by at least two of us. Sulfanilamide levels of the blood were followed in most cases. The dosage was regulated to maintain in the blood a minimum level of 50 micrograms when practicable. Uncombined sulfanilamide was quantitatively determined in the blood and

other body fluids according to the method of Fuller.<sup>6</sup> Colorimetric comparisons against known standards were made in a staphophotometer, color filter 530 being used. The drug was administered at intervals of either four or six hours, chiefly by mouth. Infections treated included those caused by the hemolytic streptococcus, meningococcus, gonococcus, *Streptococcus viridans* and pneumococcus. The diseases treated in the order of frequency were scarlet fever, tonsillitis, sinusitis, otitis, mastoiditis, lymphangitis, erysipelas, pneumonia, bacteremia, endocarditis, primary peritonitis, lymphadenitis, chronic surgical infections with draining sinuses, early abscess formation, cellulitis, infected diabetic gangrene, meningitis, puerperal fever and cutaneous infections.

TOXICITY OF SULFANILAMIDE: NO RELATION TO  
THERAPEUTIC EFFECT

At the beginning of this study the only toxic effect that had been reported was cyanosis.<sup>7</sup> We soon encountered a great many other toxic manifestations. Many of these have since been reported by other observers. All symptoms and signs referable to sulfanilamide toxicity were carefully recorded and an attempt was made to determine their possible relation to the effectiveness of the drug. Approximately half of the adults and one fifth of the children showed some toxic manifestations. Some of these have been mild and others alarming; however, none of the five deaths in this series of 250 cases resulted from drug toxicity. The toxic manifestations observed were (a) mild—cyanosis, symptoms of the gastrointestinal tract and of the central nervous system, fever, precordial and abdominal pain, and acidosis; (b) severe—rash, jaundice, anemia, hemoglobinuria, and granulocytopenia; (c) secondary reactions and late manifestations.

## MILD MANIFESTATIONS

A. Cyanosis.—The development of cyanosis in patients receiving sulfanilamide has been a common occurrence. It was noted in approximately 50 per cent of adults and 20 per cent of children in whom the drug was used. This manifestation usually began with pallor and progressed to deep cyanosis, especially marked in the lips. In some persons cyanosis developed within twelve hours; most persons became blue before the third day of drug therapy. The intensity of the color seems to depend on the amount of drug in the circulation rather than on the amount of drug administered; it was paralleled closely by the concentration of methemoglobin in the blood as measured by the spectrophotometer (an illustrative case is given in the table). Cyanosis was detectable when the methemoglobin of the blood reached a concentration of 5 per cent and was striking at about 15 per cent. The highest value obtained was about 25 per cent in extreme cyanosis. Even at these levels there were no symptoms attributable to the methemoglobinemia per se. This manifestation did not seem to be dangerous in most cases, since it disappeared rapidly following withdrawal of the drug. However, in patients with diseases accompanied by lowered arterial oxygen, either systemically or in a localized area, the question arises whether the development of methemoglobinemia may aggravate the underlying disease. This problem has presented itself in pneumonia, in cardiac insufficiency and in recovery of compromised tissues following local inflammation or injury.

The work reported in this communication was conducted under the W. K. Kellogg Foundation Fund.

From the Departments of Surgery and Medicine, Columbia University College of Physicians and Surgeons, and the Presbyterian Hospital.

The authors are indebted to the Willard Parker Hospital and Dr. John Lytle for the cases of scarlet fever. Dr. A. R. Dochez initiated this study and has given invaluable advice.

**B. Gastrointestinal Symptoms.**—A great many disturbances in physiology of the gastrointestinal tract have occurred, especially among adults. Particularly frequent have been anorexia, nausea, vomiting and abdominal pain. Diarrhea has been severe in a few cases. Like cyanosis, these symptoms have disappeared rapidly when sulfanilamide therapy has been discontinued. This problem has been particularly acute in infants, in whom essential maintenance of nutrition has been made difficult by the severe anorexia, and persistent regurgitation has sometimes been displayed.

**C. Disturbances of the Central Nervous System.**—Dizziness and headache have been fairly common symptoms of sulfanilamide toxicity among adults. Mild personality changes, especially lightheadedness and depression, have been noted in many persons shortly after beginning the drug. A few have become disoriented and even manic.

All these symptoms have subsided rapidly when drug therapy was stopped. In cases in which the condition of the patient demanded, the drug has been continued

in spite of the appearance of the aforementioned mild manifestations of toxicity. Reduction of the dosage by 25 per cent has generally sufficed to prevent the development of more severe symptoms.

**D. Sulfanilamide Fever.**—The development of drug fever has been an especially puzzling problem. This manifestation, rare in children, has been a frequent occurrence in adults. Most persons in whom sulfanilamide fever developed experienced some of the symptoms mentioned along with the appearance of pyrexia. A few, however, had pyrexia without symptoms. We have seen three different types of febrile response to sulfanilamide. The most common of these was a slowly rising temperature, occurring after the fourth day of therapy, progressing by stages each day (up to 106 F. in some instances) and falling about twenty-four hours after the drug was stopped. In some cases the temperature became normal within twenty-four hours but in most instances after forty-eight hours. In a smaller group of patients high fever and chills developed about twenty-four hours after the institution of therapy. These patients seemed to have a low tolerance for sulfanilamide. A few who had previously experienced sulfanilamide sickness showed a "hypersensitive reaction" on subsequent administrations of the drug from one month to one year later. As little as 0.6 Gm.

of the drug given to these "hypersensitive" subjects was sufficient to produce profound reactions within six hours, characterized by aches, chills, temperature spiking to 104 F., headache and leukocytosis as high as 30,000 per cubic millimeter.

**E. Precordial and Abdominal Pain.**—A few patients showed unexplained abdominal pains during the course of treatment, located chiefly in the upper quadrants. This occurred mainly in patients who were showing other evidence of toxicity from the drug, such as cyanosis or gastrointestinal complaints.

**F. Acidosis.**—One severe case of acidosis occurred in this series. Cessation of drug therapy was followed by prompt recovery.

None of the toxic manifestations discussed up to this point has seriously affected the outcome of the disease. Less frequent but much more severe are the following drug manifestations:

#### SEVERE MANIFESTATIONS

**A. Rash.**—In eight patients a maculopapular rash developed during or just after sulfanilamide therapy. The appearance was similar in all cases, resembling confluent measles. Any part or at times the entire body was involved. Itching was severe in some cases. The drug was stopped in each instance at the onset of rash because of the fear that continued sulfanilamide therapy might result in severe exfoliative dermatitis. The rash usually persisted for two days or longer, finally clearing completely.

**B. Jaundice.**—Two types of jaundice appeared; one a severe hemolytic jaundice, the other presumably a result of hepatitis. Although the jaundice subsided when the drug was discontinued, transfusions were necessary in some cases. Jaundice has been an extremely disturbing development; in view of the possibility of permanent damage to the liver, sulfanilamide was discontinued whenever it appeared. The jaundice was usually accompanied by secondary anemia.

**C. Anemia.**—Mild anemias developed in a number of cases, but it was not possible to determine with certainty whether they were due to the infection or to the drug. In a few patients, however, a severe hemolytic anemia seemed attributable to sulfanilamide. This occurred after only moderate dosage of the drug. The most intense were accompanied by icterus, the less severe by progressive anemia. In one case a large spleen and liver developed which subsided after transfusion and discontinuance of the drug. Transfusions were employed freely in anemia and seemed to counteract progression to some extent.

**D. Hemoglobinuria.**—In two patients on moderate doses of the drug hemoglobinuria developed shortly after sulfanilamide therapy was instituted. In one of these cases there was an alarming drop in the hemoglobin level.

**E. Granulocytopenia.**—Two patients, both females, had a depression of leukocytes following sulfanilamide therapy. In both these cases the infection may have been largely responsible for the granulocytopenia, and the part played by the drug cannot be accurately determined. In one instance the granulocytes disappeared completely and an alarming pyrexia developed. In both cases the final outcome was satisfactory.

#### SECONDARY REACTION: LATE MANIFESTATIONS

The drug symptoms mentioned up to this point usually appeared during the course of therapy. In one man severe sulfanilamide manifestations developed

eighteen days after the drug had been stopped, including pyrexia of 105 F., jaundice, enlargement of the spleen and liver, and a rash. It seemed perfectly definite that this patient had severe sulfanilamide sickness with hemolytic jaundice. The unusual feature was its appearance more than two weeks after the last dose of the drug.

The foregoing evidences of drug toxicity bore no observable relation to the effectiveness of sulfanilamide in overcoming infection. In some of the patients who showed marked toxic effects, the underlying infection seemed to be checked by the drug and promptly flared when the drug was discontinued. On the other hand, some patients who had toxic symptoms, such as severe cyanosis, were not benefited. The chief importance of the drug symptoms was their limiting effect on the amount of sulfanilamide that could be given. As far as the effect of sulfanilamide on the infectious agent was concerned, the presence or absence of symptoms of drug toxicity was irrelevant.

#### SEROLOGIC TYPE OF HEMOLYTIC STREPTOCOCCUS: NO RELATION TO EFFECTIVENESS OF SULFANILAMIDE THERAPY

It was not known whether all serologic types of hemolytic streptococci could be influenced by sulfanilamide or whether some were refractory to this drug. Daily cultures of the infected sites were made in most patients before, during and after chemotherapy was instituted. The organisms were typed according to the method described by Griffith.<sup>8</sup> Of the known types of hemolytic streptococci of group A, all but four were represented in this series. It was not possible to correlate the effectiveness of the therapy with the serologic type. No type seemed refractory to the drug. Moreover, human infections with organisms of Lancefield's groups C and G as well as group A seemed to be influenced by sulfanilamide therapy.

#### THE PROBLEM OF RELAPSE FOLLOWING WITH- DRAWAL OF SULFANILAMIDE

The administration of sulfanilamide was followed in a high proportion of cases by the disappearance of the infectious agent from cultures and the subsidence of signs and symptoms. The infecting organism had apparently been destroyed. In many hemolytic streptococcus infections, however, organisms which had disappeared during the course of treatment reappeared in predominance or even in pure culture within seventy-two hours of the time the drug was stopped. In most instances this was of no clinical importance. In a number of patients, however, the reappearance of the organism was accompanied by relapse. This occurred mostly in patients who had received the drug for less than ten days.<sup>9</sup> It was also noted that relapses were more common in some diseases than in others. They were frequent in patients with localized infections containing necrotic tissue, such as mastoiditis and abscesses, whereas in bacteremia and erysipelas they were not encountered. A few illustrative examples are given:

*Reappearance of Organism Without Symptoms.*—Many patients whose cultures had become negative for hemolytic streptococci had a reappearance of organisms of the same serologic type in almost pure culture

at the site of infection within three days after the drug had been stopped. This was particularly common in cases of acute pharyngitis and tonsillitis. In the majority of them convalescence proceeded uneventfully without return of fever or symptoms.

E. S., a boy aged 12 years, with mild scarlet fever, was given 2.5 Gm. of sulfanilamide a day for four and a half days. Culture on admission of material from the throat yielded predominantly the hemolytic streptococcus. Succeeding cultures showed the organism in decreasing numbers. After medication was stopped, the organisms began to increase rapidly. A week after the drug was stopped the hemolytic streptococcus was again predominant, and there was a mild temperature rise to 100.4 F. without symptoms.

*Reappearance of the Organism with Mild Symptoms.*—Some patients who showed a return of the infectious agent experienced mild symptoms of the same character but less severe than the original disease. These symptoms usually disappeared without administration of sulfanilamide being resumed. This was especially common in persons with throat infections but occurred also in other types of infections.

M. S., a woman aged 20, a student nurse with severe hemolytic streptococcus pharyngitis, was given sulfanilamide 4 Gm. for three days and 3 Gm. for two days. Culture of material from the throat the day medication was begun showed hemolytic streptococcus, type 13, predominating. Culture the day after medication was negative for the hemolytic streptococcus and continued so for a week. There was marked subjective improvement with a drop in temperature on the day following medication (perhaps coincident with rupture of an intratonsillar abscess). The patient was discharged from the hospital ten days after medication was stopped. On the same evening she had a recurrence of tonsillitis with cervical adenitis and a slight rise in temperature. Culture of material from the throat again yielded hemolytic streptococcus, type 13, predominantly.

*Recurrence of Severe Disease.*—In other patients a moderately severe disease picture developed, not unlike the original symptoms, when the drug was discontinued.

J. C., a woman aged 37, was admitted with chronic otitis and mastoiditis. Culture showed the hemolytic streptococcus. After four days in the hospital the temperature rose to 103 F. and frank signs of erysipelas developed about the ear. Sulfanilamide 4 Gm. a day was given and she showed marked improvement. The erysipelas disappeared and the temperature returned to normal. One week later she was being prepared for mastoidectomy and sulfanilamide was discontinued. After three days without the drug there was a recurrence of the erysipeloid lesion, mild fever, followed by edema of the eyelids and pain around the edge of the lesion. Sulfanilamide was again administered in the same doses and the response was similar to the original response; i. e., the temperature and cutaneous lesions disappeared in three days. The drug was continued, however, for nearly two weeks, at the end of which time no further relapse occurred.

The following cases show that patients with purulent lesions require a long course of therapy, owing to the survival of organisms in foci. In this group permanent clinical recovery seemed to depend on the development of adequate normal defenses. When this occurred, symptoms disappeared permanently, even in cases in which the individual remained a carrier of the infecting agent.

The first patient with a uterine infection required two weeks of chemotherapy before she was able to control the invasiveness of a virulent organism without the assistance of the drug.

M. C., a woman, had a postpartum infection, with a fever of 104 F. Vaginal culture showed the hemolytic streptococcus, group A, type 13, in pure culture. She was given sulfanilamide

8. Griffith, F.: J. Hyg. 34: 542 (Dec.) 1934.

9. The procedure subsequently adopted to prevent relapses has been to diminish the dose gradually over a period of days, the temperature curve being used as an index of controlled infection. Secondary courses of therapy were employed only when absolutely necessary, because of the greater incidence of severe toxic reactions in such cases.

2 Gm. the first day, and then 4 Gm. each day for one week. The temperature fell to normal within thirty-six hours. The sulfanilamide level of the blood at that time was about 30 micrograms per cubic centimeter. After one week the dosage was diminished to 2.6 Gm. Coincident with this the temperature rose, severe symptoms returned and cultures of material from the vagina became strongly positive with type 13. It was then necessary to increase the drug to the point of toxicity. The cultures of material from the vagina again became free of streptococcus when the sulfanilamide level in the blood reached 50 micrograms. After two weeks of therapy it was possible to discontinue the drug without untoward symptoms, although the patient remained a carrier for a period of months.

The next history likewise illustrates the necessity of maintaining a high level of sulfanilamide in the blood until natural resistance has had time to develop:

H. M., a young woman, was admitted to the hospital because of chills, fever and red and painful legs of twenty-nine hours' duration. On admission, the temperature was 105 F. and she showed massive edema with redness of the lower extremities and slight edema of the hands and face. There were large irregular tender blisters over the surface of the legs. It was felt that she had hemolytic streptococcus cellulitis, probably with infection of the blood stream, and sulfanilamide therapy was begun immediately. Blood culture on admission showed the hemolytic streptococcus in two flasks. Twenty-four hours after treatment the blood stream became sterile. However, cultures of the necrotic lesions on the legs were positive on the fourth day, when the blood contained 40 micrograms of sulfanilamide per cubic centimeter. The dosage was lowered on the eighth day. Three days later the temperature rose as the alarming symptoms returned and the dosage was again increased with prompt effect. It was possible to discontinue the drug during the fourth week without untoward results, although she remained a carrier.

So far as could be determined, sulfanilamide did not depress the development of the normal defense mechanism; but drug therapy was needed until the time of this development.

#### DEVELOPMENT OF METASTATIC LESIONS AND BACTEREMIA

In several patients hemolytic streptococcus metastatic lesions developed after the course of sulfanilamide therapy had been terminated, at a time when recovery was believed to be complete. In others hemolytic streptococcus bacteremia developed about thirty-six hours after the drug had been either stopped or markedly diminished in amount. In these cases the reduction in dose was prompted by the onset of mild toxic manifestations; the consequences of withdrawal were almost disastrous.

C. D., a girl aged 7 years, admitted with scarlet fever and signs of acute mastoiditis, was given sulfanilamide approximately from 2 to 3 Gm. each day. The temperature, which was 107 F. on admission, subsided slowly, keeping a range of about 100 to 101 F. In preparation for mastoidectomy, the dosage was lowered. Following mastoidectomy, the temperature rose markedly, reaching a height of from 105 to 106 F. Blood culture taken at this time showed hemolytic streptococcus of type 5, the same as the organisms recovered from the ears and throat on admission to the hospital. Sulfanilamide therapy was again started in similar doses and subsequent blood cultures all remained sterile. The temperature, however, spiked to from 103 to 104 F. for a number of days, and the patient remained acutely ill for two weeks following bacteremia. Eventually, on sulfanilamide therapy, the temperature subsided, and the patient was discharged fifty days after admission. This accident, almost fatal, followed the discontinuance of the drug.

These observations suggested that the protective action of sulfanilamide was greatest in the circulating fluids and that, after withdrawal, bacteria remaining in necrotic tissues could become highly invasive.

#### THE RELATION OF FREE SURGICAL DRAINAGE TO THE EFFECTIVENESS OF SULFANIL- AMIDE THERAPY

So far as could be determined, sulfanilamide was of no therapeutic value against well developed abscesses. In these cases surgical drainage later brought prompt relief.

We have encountered several chronic streptococcal infections refractory to surgical treatment in which the natural defense mechanism was not capable of preventing the occasional migration of organisms to new tissue. There was little immediate risk of generalized blood or lymphatic invasion, yet the antibacterial forces were not strong enough to overcome the infection. We present two cases of this type in which sulfanilamide proved highly effective. In the first case, one of long duration, the drug was continued well beyond the stage of healing, and the result was completely satisfactory, at least as far as one can judge from the follow-up period of eighteen months. In the second case, premature withdrawal of the drug following an initial satisfactory response was followed by the reappearance of streptococci in the exudates and a simultaneous flare-up in the activity of the local infection. Resumption of sulfanilamide therapy eventually cleared this infection.

M. S., a school girl aged 15 years, first admitted to the private pavilion under the care of Dr. Auchincloss Jan. 9, 1931, had had hemolytic streptococcus septicemia eleven months before, followed by pneumonia and suppurative arthritis of the right sacro-iliac joint. The latter had drained spontaneously at the right pelvic brim seven months before, and the discharge had continued intermittently ever since, inadequate drainage producing periodic spikes of fever.

Over a period of sixty-eight months, the patient continued to have almost constant suppuration in the pelvis. She had twenty-six operations during that time. It was found that constant maintenance of free drainage both anteriorly and posteriorly was essential in order to prevent the formation of new abscesses. The process later invaded the uterovesical space and produced an anterior vesical fistula, which finally closed. She either had drainage tubes constantly in place to prevent closure and backing up of pus, or else her ambulatory period was of short duration, an early recurrence of pain and fever bringing her back to the hospital.

Her last operation was on Oct. 13, 1936, when simple excision of a granulating tract in the lower anterior wall of the abdomen was done. Following the immediate postoperative period, her temperature became normal, but she continued to have fairly profuse drainage from each of three tracts, cultures showing the same type 13 (Griffith) hemolytic streptococcus which had constantly occurred in almost pure culture in her discharges.

Sulfanilamide 3 Gm. daily was started October 27 and continued until discharge November 23. The draining sinuses were irrigated with a 1.2 per cent solution of sulfanilamide in 0.5 per cent saline solution. The discharge diminished rapidly in amount after treatment was started and became thin and sticky, the granulations lining the sinuses assumed a healthy appearance, and the sinuses filled in rapidly from the depths. It appeared on purely clinical grounds to Dr. Auchincloss, who had had the patient under almost constant observation for five and a half years, that a type of healing was taking place which he had never observed in this patient's wounds. A follow-up period of eighteen months has now passed without any evidence of recurrent disease. After discharge from the hospital, she continued to take from 1 to 2 Gm. of sulfanilamide daily for about one month. At no time were serious symptoms or signs of toxicity noted.

L. B., a woman aged 26, a telephone operator, complained of ulceration of the pectoral region for ten months. At that time an abscess had developed in the right breast which had been incised and drained but failed to heal. Spreading and undermining continued in spite of repeated surgical procedures in

several hospitals. The patient had had some fever most of the time and a great deal of pain. On examination the patient was emaciated with extensive ulceration of the right pectoral region, the right breast being attached by only a short pedicle of skin beneath the clavicle. There was undermining of the skin peripheral to the ulcer, and three "daughter ulcers" had formed in the pectoral and infraclavicular regions. Exudate was profuse and foul. Cultures showed hemolytic streptococci.

With no operative intervention the patient was started on sulfanilamide 4.5 Gm. daily. After nine days the cultures showed no hemolytic streptococci and marked clinical improvement had occurred, so that the drug was stopped when the patient became nauseated. After six days without sulfanilamide there was an increase in the amount of discharge, the wound looked worse and cultures showed reappearance of streptococci. The drug was resumed and rapid improvement again occurred, although this time the disappearance of the hemolytic streptococci from the wound was slowed. During the next twelve weeks she continued to receive sulfanilamide, though most of the time the usual daily dose was only 2.5 Gm. During the fourteen weeks of hospitalization it was possible to perform a plastic operation, with excision of contracted scar tissue and resuture of the breast to the chest wall. This healed uneventfully and the patient was discharged.

Both of these chronic infections were treated successfully. In the presence of sulfanilamide the organisms were unable to form metastatic lesions. Free surgical drainage permitted elimination of pus. The combined treatment gradually eliminated the organisms, which had persisted deep in the wounds for a long time. In the first of these cases most of the necrotic tissue which might have served as a protected nidus for persistent infections had been surgically removed. In the second case there was little deep necrosis when treatment was started.

#### THE RELATION OF MIXED INFECTIONS TO THE EFFECTIVENESS OF SULFANILAMIDE THERAPY

In necrotic lesions in which both hemolytic streptococci and hemolytic staphylococci occurred, drug therapy was often ineffective even in the presence of free surgical drainage. The staphylococci in local lesions were not influenced by sulfanilamide. The continuation of purulent lesions with this organism seemed to inhibit the chemotherapeutic effect of sulfanilamide on hemolytic streptococci.

A. McL., a housewife aged 37, had an indolent infection of the interphalangeal joint of the left thumb which was observed for several days in the outpatient department. She was finally admitted for incision and drainage, at which time cultures from the joint space showed hemolytic streptococci. Sulfanilamide was started on the fifth day after operation in order to see whether rapid elimination of the streptococci could be effected. On the seventh day *Staphylococcus aureus* as well as streptococci was found in the exudate, and these two organisms persisted in the wound for three weeks in spite of continued sulfanilamide. Little effect on the character of the lesion was obtained by local irrigation with sulfanilamide solution.

The possibility suggested itself that the staphylococcal activity created environmental conditions which interfered with the effect of sulfanilamide on the streptococcus.

#### THE EFFECT OF SULFANILAMIDE ON RAPIDLY SPREADING INFECTIONS

Sulfanilamide therapy seemed most effective in rapidly spreading lesions in which there had been little tissue destruction:

J. I., a man aged 31, an apartment house superintendent, was admitted with extensive cellulitis of the left hand twenty-four hours after introduction of a splinter of manila rope into

the middle finger. The temperature was 103 F. on admission. In spite of the very short time since the primary injury, there was a well developed pattern of lymphangitis extending to the shoulder. There was exquisite tenderness and swelling around the site of the splinter wound, but no signs of tenosynovitis were present. An exploration of the superficial layer of skin around the wound was made to see whether any foreign body was present, but incision of the closed spaces of the finger was not done because of the unlocalized character of the infection. Sulfanilamide was started, wet dressings and elevation were instituted and, within twenty-four hours, subsidence of spread of the lesion had definitely commenced. On the fifth day the temperature returned to normal. On that day, signs of localized abscess were noted and the middle closed space of the middle finger was incised. A small drop of pus was obtained which showed hemolytic streptococci. Further recovery and wound healing were uneventful. Blood cultures throughout were negative.

This patient recovered promptly from a dangerous infection. The therapeutic effect of the drug was striking in the newly invaded tissues; however, a small abscess which developed continued to yield viable organisms in spite of sulfanilamide therapy.

A second case illustrates the effectiveness of sulfanilamide in preventing invasion into the meninges and its inability to sterilize necrotic tissue:

C. S., a boy aged 4 years, was admitted to the Babies Hospital because of intermittent earache and headache for three weeks. On lying down he complained of pain in his head, which was relieved on sitting up. There was an extensive, soft, fluctuant, exquisitely tender swelling over the right parietal region over the occipital bone. The right tympanum was white and bulging posteriorly; surface vessels were prominent.

On the day of admission a right simple mastoidectomy was performed. Near the sinodural angle there was a collection of creamy pus. The dural plate and mastoid cells in this region were soft. Pus continued to appear in such a steady stream that it was necessary to remove an area of bone extending about an inch toward the occiput. The dura was shaggy, thickened and inflamed and the brain beneath was soft.

He stood the operation fairly well and was given a small transfusion afterward. The temperature reached 103 F. on the two following days. Culture of the pus from the epidural abscess showed a pure culture of hemolytic streptococcus. Sulfanilamide was begun on the second day after operation and continued for three weeks (2.5 Gm. a day).

On the fourth and fifth days he was afebrile, but the temperature began to rise at the end of the first week and continued elevated through the second week. A superficial incision at this time released more pus, and the temperature fell to normal. He continued afebrile during the fourth week, when sulfanilamide was stopped. He was discharged after six weeks.

At home he appeared to be well for a period of ten days, without fever or complaint. On the eleventh day he awoke at 1 a. m., feverish, complaining of headache. He was brought to the hospital and while in the clinic had a generalized convulsion lasting two minutes. He was readmitted with a temperature of 104 F. The previously operated area was explored for brain abscess; none was found. However, necrotic bone was removed from two sites; each contained a pure culture of the hemolytic streptococcus. Throughout the second admission he received 2.5 Gm. of sulfanilamide a day until the ninth week, when the dose was reduced to 2 Gm. He was discharged after nine weeks, having made a satisfactory recovery.

Sulfanilamide prevented further spreading of this dangerous infection but was unable to kill organisms in necrotic bone.

A third case shows that under some circumstances the use of sulfanilamide in a rapidly spreading lesion may lead to the formation of a sterile abscess:

B. Z., a school boy aged 16 years, was admitted with hemolytic streptococcus septicemia associated with pansinusitis. He was desperately ill, with a temperature of 105 F., and showed a diffuse cellulitis of the right temporal region. On the day of

admission signs of acute suppurative arthritis of the right shoulder developed. Under sulfanilamide therapy his blood became sterile within forty-eight hours. The signs of cellulitis of the temporal region subsided, leaving a localized, fluctuant area which, when opened, yielded sterile pus on repeated cultivation. The shoulder signs and symptoms disappeared without surgical intervention. The data are given in the accompanying table.

Sterile abscesses were found in two other patients treated with sulfanilamide. In all three cases treatment was instituted before localization had occurred. It appeared that sulfanilamide sterilized the lesions when administered before necrosis of the tissue had taken place.

Finally, another case illustrates the effectiveness of sulfanilamide in a rapidly spreading infection and its ineffectiveness in a localized lesion:

M. K., an infant aged 11 months, was admitted in the early stages of acute primary hemolytic streptococcus peritonitis with septicemia. Blood and abdominal paracentesis yielded a pure culture of the hemolytic streptococcus. Under sulfanilamide therapy the blood became sterile and the signs of peritonitis disappeared after one week. No localized peritoneal abscess formed.

During the second week a suppurative phlebitis developed around an infusion cannula in the saphenous vein, and coincident with this blood culture became positive. Because of suspected hepatitis, sulfanilamide was withheld for twenty-four hours and the colony count rose from 10 to 1,328 per cubic centimeter in the blood culture. Sulfanilamide therapy was resumed and an abscess which formed at the site of the phlebitis was drained. Examination of the pus showed hemolytic streptococcus in pure culture. The blood became sterile and remained so. Recovery was complete, and the patient has enjoyed good health during the follow-up period of fourteen months.

Sulfanilamide sterilized the blood stream and the peritoneal cavity in this critically ill infant. However, in the presence of traumatized tissue and hematoma formation sulfanilamide was unable to sterilize a localized infection. Organisms in this focus remained highly virulent but were unable to form metastatic lesions elsewhere in the presence of a high level of sulfanilamide in the blood.

#### SULFANILAMIDE THERAPY: NO EFFECT ON IMMUNE BODY FORMATION

That sulfanilamide may have toxic effects on the liver, spleen and bone marrow has been pointed out. Whether this drug might depress or stimulate antibody formation was unknown. To determine this, two types of studies were made.

The first of these consisted in serial determinations of antistreptolysin over a period of from thirty to sixty days after infection. This antibody to the streptococcus was examined because it permits quantitative measurement and because previous experience had indicated the normal curves in untreated infections. Samples of blood were obtained at intervals of from two to seven days, and the antibody curves for approximately 100 patients receiving sulfanilamide were determined. On the whole, the curves were similar to those of untreated patients.

The second study was made on guinea pigs. Serial determinations of antistreptolysin were made on animals given agar foci, inoculated with varying doses of hemolytic streptococcus, N Y 5 (0.0001, 0.1 and 0.5 cc. of eighteen hour broth cultures) and treated for varying periods (two, three and four weeks) with sulfanilamide (5 cc. of a 2 per cent solution twice daily). Thirty-two pigs were treated with sulfanilamide; eight

controls were untreated. The hemolytic streptococcus was recovered from the abscesses of all pigs but one. In the treated pigs that survived for two weeks after infection, antistreptolysin levels developed similar to those in the controls. One control pig failed to form the antibody. There was no indication that sulfanilamide had any effect on production of antistreptolysin.

#### COMMENT

The clinical aspects of this study showed striking differences in the effectiveness of sulfanilamide. These differences were related more to the character of the lesion than to the identity of the bacterial infection. Sulfanilamide was most effective in bacteremia, lymphangitis, erysipelas and cellulitis; it was highly effective in early infections with little suppuration. It had a questionable effect in scarlet fever, tonsillitis, sinusitis, otitis and mastoiditis. The drug was ineffective when abscesses were well established, except perhaps in limiting their further spread and protecting normal surrounding tissues against invasion when drainage was used.

So far as could be determined from scarlet fever, the drug had no effect on toxemia of streptococcal origin. It is possible, however, that the symptoms in these persons were due to toxin absorbed before sulfanilamide therapy was instituted. The majority of strains of hemolytic streptococci showed little change in their production of hemolysin following sulfanilamide therapy. In a few organisms, however, production of hemolysin was strikingly inhibited. It seemed to us that any depression in the production of soluble toxins was of secondary importance.

The striking effect of sulfanilamide was a depression of the invasive properties of the organism. This effect was definite within eighteen hours in the case of bacteria circulating in tissue fluids or in newly invaded tissues.

In contrast, the presence of debris, human or bacterial, diminished the effectiveness of sulfanilamide on the hemolytic streptococcus. In each instance the organisms remaining in broken down tissue maintained their virulence. It is not known whether the debris itself had a protective action on the organisms or whether there was insufficient penetration of the drug into the locus.

It seems possible that sulfanilamide may alter the total metabolism of the micro-organism or may interfere especially with some specific function, such as its capacity to digest protein. In either case the presence of necrotic tissues appears to be of great importance. Sulfanilamide should be considered an agent which supplements, and in no way supplants, antibacterial immunity. These aspects of the problem are now under experimental investigation by one of us (J. S. L.) and will be the subject of a forthcoming report.

#### CONCLUSIONS

The effectiveness of sulfanilamide therapy is related to the type of lesion.

The function of the micro-organism, which is strikingly depressed by sulfanilamide, is its capacity to invade tissue.

The effect of the drug on bacterial invasiveness seems to be influenced by the amount of debris present in the lesion.

These phenomena are being investigated experimentally to determine the mode of action of sulfanilamide.

PSEUDOHYPERTROPHIC MUSCULAR  
DYSTROPHY

## AN EVALUATION OF RECENT STUDIES

LOUIS SCHEMAN, M.D.

PHILIP LEWIN, M.D.

AND

SAMUEL SOSKIN, M.D.

CHICAGO

The treatment of pseudohypertrophic muscular dystrophy has passed through many cycles, depending on the prevailing theory of pathogenesis. Each has had a short period of usefulness which ended when failure to produce enduring clinical improvement made it no longer tenable. At present the myodystrophic patient will probably pass through the entire gamut of therapy, beginning with the more recent forms and working backward as each in turn is discarded as ineffective.

For a time all interest centered on endocrinologic factors,<sup>1</sup> and practically every gland was incriminated. The pineal and pituitary<sup>2</sup> glands were particularly singled out by many workers, who pointed to a similarity of symptoms in diseases of these ductless glands to those found in the dystrophic patient.

In medical writings repeated emphasis is placed on a supposed disturbance in carbohydrate metabolism.<sup>3</sup> These statements are based on chemical studies<sup>4</sup> and on deductions drawn from the occurrence of creatinuria in unrelated conditions such as diabetes and starvation.

Occasionally a sporadic case of pseudohypertrophic muscular dystrophy is reported occurring as a post-encephalitic residuum or following acute anterior poliomyelitis.<sup>5</sup> This has led some writers to hypothesize a lesion in a hypothalamic center.

In 1930 Kuré and Okinaka<sup>6</sup> began treating their patients with epinephrine and pilocarpine, basing their therapy on the belief that the disease had its origin in a lesion of the autonomic nervous system. They reported very encouraging results, varying from startling improvement to a retardation or halting of the progress of the disease.

Hough and others in this country followed along these lines and reported good results. Our experience with this form of therapy has been disappointing.

Beginning with the work of Milhorat, Techner and Thomas<sup>7</sup> in 1932, the literature was studded with enthusiastic reports on the use of aminoacetic acid in

the treatment of the primary myopathies, particularly pseudohypertrophic muscular dystrophy and myasthenia gravis. Along with Tripoli and Beard,<sup>8</sup> Boothby<sup>9</sup> and others, we too obtained encouraging results. As our experience with amino acid therapy progressed, however, it became apparent to us that the progress of the disease remained unaltered and that temporary improvement, if any, was short lived in the face of advancing atrophy and fibrosis.

Our interest was again revived on learning of the recent work of Meldolesi<sup>10</sup> in Italy, covering a period of nine years and based on more than 100 cases. The theory advanced by this worker is that the muscular dystrophies are caused by a primary disease affecting the pancreas, as a result of which tryptic and lipolytic digestive processes are markedly impaired. Failure of adequate protein absorption causes a depletion of protein reserves resulting in a dysplasia of striated muscle. This occurs in persons showing a hereditary and familial diathesis the basis of which is a lack of pigment of the muscles.

More specifically Meldolesi reported that the curves for the secretion of lipase, diastase and trypsin were delayed in their rise and did not reach normal levels. Many patients showed a diminished dextrose tolerance. The feces contained an increased amount of neutral fats and fatty acids. The urines showed a total excretion of nitrogen which was low and independent of the intake of protein before therapy was started and showed a rapid rise under treatment. Following the institution of therapy, creatinuria rapidly diminished until within a few weeks a negligible amount was excreted. Similarly the excretion of creatinine increased in a rapid progressive way until it made up almost the whole fraction of the total creatinine. Treatment was directed toward correcting the deficient digestion of protein and altered carbohydrate metabolism.

Meldolesi's treatment was essentially the administration of from 40 to 60 drops of pepsin-pancreatin (a product of Richter of Budapest) twice a day, insulin and intravenous dextrose.

In the present work we attempted to determine the soundness of several of Meldolesi's basic contentions, namely:

1. That these patients are unable to digest proteins because of a lack of or deficiency in their tryptic ferments.
2. That, because of this deficiency, excretion of urinary nitrogen is independent of variations in the intake of protein nitrogen.
3. That these patients have a disturbed carbohydrate metabolism as evidenced by a diminished tolerance for dextrose.
4. That creatinuria is progressively abolished following institution of therapy.

## MATERIAL AND PLAN FOR THIS STUDY

A small group of patients was admitted to the Max Pam Unit for Metabolic Research, where they could be studied intensively under controlled conditions. This seemed to us more desirable than ordinary hospitali-

Dr. Scheman is Merriel Abbott Fellow in Orthopaedic Surgery, Michael Reese Hospital.

This research was made possible by a grant from the Merriel Abbott Fund for Crippled Children. The work was carried out in connection with the Max Pam Metabolic Unit of the Michael Reese Hospital. Dr. Werner Lehman and the Physical Therapy Department of the Michael Reese Hospital gave valuable assistance.

zation of a larger group, in which the amount of study would be necessarily restricted.

Five patients were selected, each of whom had been under observation for several years and had passed through the gamut of the more recent forms of therapy. Two of these patients were typical examples of the Duchenne type. Two belonged to the same group but presented a variant in the form of a superimposed Froelich's syndrome. The fifth also was of the Duchenne type but presented in addition a facial component such as occurs in the Landouzy-Dejerine type. The onset in each case occurred before or at about 6 years of age. Three patients were no longer ambulatory and the remaining two were markedly limited as to activity.

In cooperation with our metabolic unit it was proposed to determine on a quantitatively and qualitatively fixed diet:

1. The state of digestion, especially of proteins and fats, as indicated by examination of the stool.
2. The tryptic activity of the duodenal contents.
3. The daily excretion of nitrogen in the urine and its behavior with changes in the intake of nitrogen.
4. The dextrose tolerance.
5. The daily excretion of creatine and creatinine.
6. Variations in the foregoing data following therapy.
7. The clinical effect of therapy.

RESULTS AND ANALYSIS OF DATA

*Stool Examinations.*—In three of the five cases, stools on repeated examination were normal in gross appearance and microscopically. Muscle fibers, when present, were well digested, and fat globules could occasionally be demonstrated in a finely emulsified state with sudan III stain. In the remaining two cases the stools were unusual in the amount of grossly undigested material, which on microscopic examination, however, proved to be almost entirely vegetable in nature. There was no evidence, even in the latter cases, of disturbed digestion of meat or fat constituents of the food.

*Tryptic Activity of the Duodenal Contents.*—Successful intubation of the duodenum was performed in three of the five cases and determinations of tryptic activity made on the fasting contents and on the aspirations following stimulation with 20 cc. of twentieth normal hydrochloric acid.

We did not attempt to obtain prolonged secretory curves. A study of the aspirated contents of the duodenum convinced us that, unless aspiration by continuous suction of the gastric contents is maintained, dilution of the duodenal contents is sufficient to detract from the significance of a secretory curve. Therefore, normal values obtained at any period of the experiment were considered evidence of adequate secretion. Control values in normal children served as the basis for comparison.

In the second patient the fasting content showed normal tryptic activity. Specimens obtained thirty minutes and one hour later showed extremely low values.

The third patient showed normal initial values in both trypsin and lipase. Specimens one-half hour and one and one-half hours after introduction of twentieth normal hydrochloric acid gave tryptic values two and two and one-half times the initial level. Lipolytic activity maintained its fasting level.

*Dextrose Tolerance.*—This test was performed on four of the five patients, the intravenous method of administration of dextrose being used to obviate variations in results due to unknown factors of absorption. We used the Somogy modification of the Shaffer-Hartman method for true blood sugar. Normal limits for the fasting blood sugar level by this method are given as from 60 to 90 mg. per hundred cubic centimeters. The results are shown in table 1.

Fasting blood sugar levels of all four patients are well within normal limits. In all cases the ability to remove dextrose from the circulation does not appear to be impaired.

*Excretion of Nitrogen.*—Total excretion of nitrogen was determined in specimens of twenty-four hour urine collected under toluene under varying conditions of food intake. Results in one of the more advanced cases are shown in table 2 and are representative of the uniform response of the entire group.

It will be noted that the total excretion of nitrogen in the urine varies directly with the intake of protein.

On the various dietary regimens, which varied particularly as to protein and carbohydrate, each of the five patients consistently maintained a positive nitrogen balance.

*Excretion of Creatine and Creatinine.*—The effect of dietary variations on these urinary constituents was noted in daily specimens of twenty-four hour urine. The effect of changes in the intake of protein and of administration of large amounts of carbohydrate and insulin are noted in table 3.

From table 3 it can be seen that both creatine and, to a lesser extent, creatinine follow closely the curve of the excretion of nitrogen. Total nitrogen as in table 2 bears a direct relationship to the intake of

protein. It is interesting to note that creatine and, to a lesser extent, creatinine, when expressed as percentage of total nitrogen, bear an inverse relationship to the latter. This will be discussed later.

*Effect of Pancreatin Therapy on Excretion of Creatine and Creatinine.*—The two patients showing some disturbance in digestion were selected for this experiment. One was treated for sixty-seven days and the other for forty-four days with a concentrated enteric coated pancreatin preparation.<sup>11</sup> The results in the latter patient are representative and are presented in table 4.

In neither patient did creatinuria tend to diminish with the administration of pancreatin. Its excretion was similar to that seen in table 3, in which experi-

11. Dr. David Klein of the Wilson Laboratories supplied the enteric coated pancreatin used in this study.

ment the patients received no pancreatin; i. e., it varied directly with urinary total nitrogen. Nor did the excretion of creatine compose a smaller fraction of the total creatinine.

*The Effect of Therapy as Judged Clinically.*—In estimating clinical results a quantitative expression of the patient's muscle power was sought. It seemed quite apparent from past experience that testimonial evidence from whatever source obtained was worthless. A series of test exercises involving the performance of definite coordinated muscle actions was therefore outlined for each patient, the ability of the patient to repeat them being noted. These quantitative figures served as an index of muscular endurance. Other test exercises were devised to determine the maximum initial performance. These records were obtained twice each week by the same trained physical therapist and were maintained for a period of nine months.

The clinical results following pancreatin therapy, administration of dextrose and insulin and of insulin alone, variations in diet from low protein to high protein and similar variations in intake of carbohydrate were evaluated on the basis of the curves obtained on tabulation of muscular performances.

When creatine and creatinine are expressed in terms of the percentage of total nitrogen excreted they bear an inverse relationship to the latter. Diminution in the intake of protein causes a fall in total excretion of nitrogen and that fraction of the latter which represents exogenous creatine and creatinine. Endogenous catabolism remaining the same, the excretion of creatine and creatinine derived from it makes up a disproportionate fraction of the total excretion of nitrogen and hence bears an inverse relationship to the latter in terms of percentage. This is most strikingly seen when the protein sparing action of large amounts of carbohydrate is involved.

For years it has been believed that there is in this disease a disturbance in glycogenesis, and on this thesis feeding of carbohydrate alone or with insulin have formed a part of the therapeutic regimen in many clinics. The striking manner in which administration of carbohydrates stops the creatinuria of starvation has been offered as corroborative evidence. In our chemical studies of the blood we cannot find support for these ideas nor have we noted any correlation of clinical improvement with periods of high ingestion of carbohydrate.

\* Values include 50 Gm. of dextrose-intravenously by slow drip.

All the patients studied showed a slow progressive improvement in their ability to perform the tests outlined. However, this improvement bore no apparent relationship to the institution of various forms of therapy, including pancreatin, nor did it decline when treatment ceased. Improvement was most marked in the muscle groups most affected by the disease.

COMMENT

It appears from the results of these experiments that the patient with pseudohypertrophic muscular dystrophy does not lack the ability to digest proteins or to transform these proteins into the end products of ferment activity. There is apparently no disturbance in the formation of creatine, as one can readily note from the definite and proportionate manner in which creatinuria follows nitrogenous intake. For a long time it was felt that both creatine and creatinine had their origin solely in endogenous metabolism,<sup>12</sup> but our results and those of other investigators<sup>13</sup> indicate that there must also exist an exogenous source. The myo-dystrophic patient is a better subject for the study of creatine metabolism than the normal person and in excretion of creatine is analogous to the diabetic patient as regards dextrose. Added proof of the dual origin of creatine is suggested in the analysis of table 3.

From a purely clinical standpoint it has been our experience that no form of therapy available at the present time acts in a specific way to halt the progress of this disease. The patients included in this report have shown definite improvement in their ability to perform their test exercises, but this progress could not be correlated with any specific form of therapy employed. Had treatment remained constant in nature we would have felt justified in claiming a certain

degree of success for it. We attribute the improvement in these patients to the prolonged period of hospitalization, which included adequate diets, and, what is perhaps more important, to the regulated daily routine and physical activity, including that involved in the performance of the test exercises. That regulated exercise is of importance was pointed out long ago and becomes apparent when one notes the harmful

effect of restriction of activity such as follows biopsy of the gastrocnemius muscle. Such treatment, however, offers little of lasting value in the face of the seemingly inexorable inroads which this disease makes on the muscle.

What then is the path of the future? Recent work has taught us much of the physiology of muscle and has clarified some of the intricate mechanisms involved.<sup>14</sup> We know that creatine plays a vital part in the initiation of muscular contraction and that it occurs in loose combination with phosphorus. From a study of the chemistry of dystrophic muscles, Nevin<sup>15</sup> has shown that the usual breakdown of creatine-phosphoric acid does occur, differing but quantitatively from the normal. The ability to resynthesize this compound to its initial value also is retained. Differences are apparently quantitative rather than qualitative, and one is inclined to study more closely the known constituents of muscle to ascertain whether any substance is markedly deficient.

Such a deficiency has been noted clinically to exist in the coloring of the dystrophic muscle. Muscle pallor has been recently emphasized by Meldolesi.<sup>16</sup> This lack of adequate coloring led us to a review of the literature on muscle pigment and we found that the substance had been almost entirely forgotten in the study of the intricate processes which comprise the chemistry of muscle.

In 1887 MacMunn<sup>16</sup> described a number of tissue pigments, naming the one found in muscle myohematin. Gunther<sup>17</sup> in 1921 spoke of myoglobin and recognized that the pigment was not identical with hemoglobin. Kuhne<sup>18</sup> twenty years before MacMunn presented evidence to show that this muscle pigment had a respiratory function. More recently the study of this pigment has been carried on intensively and its isolation in animals has been accomplished by Theorrel<sup>19</sup> and later by Watson.<sup>20</sup>

As yet no place has been found for this substance in the economy of muscular contraction. It seems unlikely that nature has provided skeletal muscle with a substance which has tremendous oxidizing properties<sup>21</sup> (ten times that of hemoglobin) unless this substance plays an important role in the chemistry of muscular contraction. Eggleton<sup>22</sup> has shown that creatine diffuses rapidly from fatigued muscle and that this diffusion ceases when oxygen is supplied. In the lungs there is provided a delicate network of capillaries closely associated with specialized alveolar epithelium for gaseous exchange. In the muscle, where there must occur a rapid diffusion of oxygen from the capillaries, it would seem that a substance such as myoglobin would be essential. That myoglobin may indeed supply this mechanism has recently been shown by Millikan,<sup>23</sup> who by photoelectric spectroscopy has proved that it acts as a short-time oxygen store in the muscle to tide it over periods of oxygen want in each contraction.

We feel that when more is known of the place this pigment substance occupies in the economy of muscular

processes we shall have found an important clue to the treatment of the myodystrophic patient. Quantitative and qualitative studies of the myoglobin content of muscles in various pathologic states and their correlation with known facts of the chemistry of these muscles will be necessary to evaluate the clinical importance of myoglobin. Such studies are in progress.

#### SUMMARY AND CONCLUSIONS

1. Five patients with pseudohypertrophic muscular dystrophy were studied to determine whether a deficiency in the external secretion of the pancreas forms a part of the syndrome.
2. No evidence could be found from a study of the stools, duodenal contents and urine that the pancreas is involved.
3. Improvement while under observation was found to be unrelated to specific treatment.
4. It appears that muscle pigment or myoglobin is of importance in the economy of muscular processes.

### THE TREATMENT OF CARDIAC IRREGULARITIES

GEORGE FAHR, M.D.

MINNEAPOLIS

One of the most experienced cardiologists<sup>1</sup> has estimated that serious cardiac failure is accompanied by auricular fibrillation in more than half the cases. Experienced practitioners know that extrasystoles are at least as frequent in cases coming to a doctor's office. Therefore it becomes apparent that the treatment of the cardiac irregularities is one of the important services rendered by the physician to his clientele. Moreover, the treatment of the cardiac irregularities is today, comparatively speaking, very efficacious and easily carried out.

I shall first discuss the treatment of auricular fibrillation because this makes up nearly one half of all the cases of cardiac irregularity that one has to treat and because it has a very harmful effect on the pumping mechanism of the heart. Eyster and Swarthout<sup>2</sup> have shown that the mere presence of auricular fibrillation in a dog's heart reduces the output of the heart by an average of 40 per cent and reduces the blood pressure on an average of 35 per cent. Lewis<sup>3</sup> demonstrated that auricular fibrillation not only reduces the output of the heart but also may increase the venous pressure even in an animal with an otherwise normal heart. These experiments indicate that the appearance of auricular fibrillation in hearts with a valvular defect or with a damaged myocardium is a most serious occurrence. Every experienced physician has noted that patients with mitral stenosis often do very well for many years but that the onset of the absolutely irregular pulse, which is synonymous with auricular fibrillation, brings about cardiac failure, which from that time on is present in some degree unless the auricular fibrillation is properly treated. I have seen athletes performing creditably in competition despite the pres-

ence of a mitral stenosis. But as soon as auricular fibrillation began, symptoms of breathlessness and dropsy appeared and from that time on the former athlete was more or less of an invalid and could at the best carry out duties entailing only very moderate exercise.

In man, the effect of untreated auricular fibrillation is largely to increase the venous pressure and to decrease the output of blood leaving the ventricles during each minute. Through the influence of vaso-motor adaptation, the tendency for blood pressure to drop is usually counteracted. The reduction in ventricular output is due largely to the rapid rate of the ventricles, to the large number of premature and abortive contractions of these chambers and to auricular paralysis. Digitalis given in sufficient amounts will reduce the ventricular rate to the optimum, and in reducing the rate of the ventricles the number of premature and abortive contractions becomes very small indeed. It is therefore by partially blocking conduction from the fibrillating auricles to the ventricles that digitalis brings about its remarkably favorable influence on the heart in auricular fibrillation.

When one sees a patient with auricular fibrillation for the first time, the ventricles are usually beating with an absolutely irregular rate of from 100 to 160 beats a minute. The exhibition of sufficient amounts of digitalis will reduce the rate of the ventricles to a value of from 60 to 70 beats a minute, which in most adults I find to be the optimal rate when auricular fibrillation is present. The effect on the patient is remarkable. As a rule, as soon as the rate is reduced to the optimal value the patient's dyspnea lessens, tenderness and enlargement of the liver recede, edema begins to become absorbed and to be excreted by the kidneys, and the cyanosis tends to diminish. The increased venous pressure, which is the main factor in causing the symptoms of dyspnea, edema and swelling of the liver, drops to normal values; measurements of circulation time and of minute volume show that the output of the heart has approached the normal, even when serious valvular defects and myocardial damage are present.

It is true that digitalis increases the mechanical efficiency of the heart muscle fibers, as Visscher<sup>4</sup> has shown, but when auricular fibrillation is present the reduction in the ventricular rate is at least as great a factor in bringing about compensation in cardiac failure, if not a greater one.

#### METHOD OF GIVING DIGITALIS

There has been a great deal of discussion as to the method of giving digitalis, and I shall spend some time in discussing this, emphasizing the methods that have proved themselves of great value in the treatment of a large number of cases at the Minneapolis General Hospital and at the University outpatient heart clinic. I shall discuss mainly the use of preparations of digitalis purpurea for preparations of this drug are now carefully standardized in terms of the cat unit.<sup>5</sup> This drug

4. Visscher, M. B.: *The Energy Metabolism of the Heart in Failure*, Minnesota Med. 21:85 (Feb.) 1938.

5. A cat unit as used in this paper is the amount of drug per kilogram of body weight necessary to kill a cat in one hour under the standard conditions of the original Hatcher-Brody method. The cat unit as determined by other methods such as the Magnus differs considerably from the Hatcher-Brody cat unit. The value of the cat unit lies in the fact that the body weight of the patient, one can calculate necessary to obtain the optimal digitalis effect the level of toxic effects of the drug. Maintenance dosage can also be expressed in cat units per day. At present digitalis is standardized according to the U. S. P. XI so that 0.65 cc. of the tincture or 0.065 Gm. (1 grain) of the powdered leaf is 1 Hatcher-Brody cat unit. In the previous editions of the U. S. Pharmacopeia 1 cc. of tincture or 0.1 Gm. of the powdered leaf contained 1 cat unit. One-tenth Gm. (1½ grains) of the standard U. S. P. XI powder is equivalent to 1.6 Hatcher-Brody cat unit.

has now been so thoroughly studied that it is known approximately how much a patient should be given to get a desired effect and just about what the toxic dose for a given patient is. I shall mention briefly the use of preparations from digitalis lanata. In my opinion 1 cat unit (0.65 cc. of tincture or 0.065 Gm. [1 grain] of U. S. P. powdered leaf) to each 10 pounds (4.5 Kg.) of body weight when anchored in the body gives very nearly the optimal effect in lowering the ventricular rate in auricular fibrillation. It is also with but rare exceptions a perfectly safe amount. If this amount does not effect the desired lowering of the ventricular rate, a little more (from 10 to 30 per cent) most certainly will. On the other hand, not more than one patient in fifty will show signs of digitalis intoxication with this amount, and the degree of intoxication will not be serious. Stopping the administration of digitalis for from twenty-four to seventy-two hours will relieve the symptoms of intoxication and no harm will have been done. Moreover, the administration of 1 cat unit a day will on the average hold the ventricular rate of a patient weighing 150 pounds (68 Kg.) at rest and free from nervousness at the optimal point. In other words, the anchored digitalis is removed from the body at the rate of approximately a cat unit a day. Doses of digitalis of this size will not reduce the volume flow through the coronary arteries nor injure the myocardium. One cat unit a day may be given to the 150 pound patient for years without danger. If vomiting necessitates rectal administration, the same dose is to be given as for the oral administration.

Whether one uses tincture or whether one uses pills or capsules of the powdered leaf is in my opinion immaterial provided the tincture is fresh and is standardized accurately. As a rule equally good results will be obtained by the two forms of the drug.<sup>6</sup> If the patient is only moderately decompensated, seven days may be taken for optimal digitalization. In this case 21 cat units would be given to a patient weighing 150 pounds to be used up in seven days: 6 cat units to supply the loss of digitalis in the six days following the day on which the drug is first given and 15 cat units for the optimal amount to be anchored in the body.<sup>7</sup> It is well if the patient can be seen by the physician daily, but many of our dispensary patients are not seen until the week has passed. If the ventricular rate is above 70 when the patient returns and is resting quietly in the examining room and is not excited, we give 2 cat units a day until the heart rate is between 60 and 70 beats a minute. When this rate has been reached, we give 1 cat unit a day. It is best if the physician can see his patient every day or two to control the rate by giving a little more or a little less digitalis for the next four weeks, but many of our patients cannot return for one or two weeks, and it is rare not to find the pulse rate approximately the same. A little more or a little less digitalis will bring about the desired rate (60-70).

In our dispensary practice we often give the calculated optimal amount within a shorter period if the patient is badly decompensated. For example, we frequently give a patient weighing 150 pounds 17 cat units throughout a three day period, during which time a

6. The tincture should not be given in drops but the required amount should be measured out in a measuring glass. I prefer to mix 0.6 cc. of tincture of digitalis with 3.4 cc. of aromatic elixir and give this fairly pleasant mixture in this dose, each drachm (4 cc.) representing 1 cat unit.

7. Assuming that the patient has had no digitalis for at least three weeks. If the patient has had digitalis recently, 2 cat units a day is given until the pulse rate reaches 60-70.

visiting nurse counts the ventricular rate with the stethoscope during daily visits to the patient's home or to a rest home in the city if the patient is from out of town. The nurse reports late each afternoon to the physician in charge of the case.

When the patient returns on the third day, the dispensary physician gives 1 or 2 cat units a day for the next three days, depending on whether the ventricular rate is in the neighborhood of 60-70 or higher. Given in this way we have seen digitalis poisoning occur only infrequently, and we have yet to see the first case of dangerous intoxication. On the other hand, the results on the ventricular rate have nearly always been excellent.

In our hospital practice we usually attempt to get the optimal result more quickly. As a rule we give 15 cat units to the 150 pound patient within the first thirty-two hours, one third of the calculated amount being given at once and one sixth every eight hours for four doses. An attempt is made to hold the ventricular rate at the optimal point by the exhibition of 1 cat unit a day if the optimal rate has been reached at the end of from forty to forty-eight hours. If this rate has not been reached we give 2 cat units a day until the rate is between 60 and 70. After this 1 cat unit a day will usually hold the rate at this point. It may be necessary to give a little more or a little less, but if the patient is seen each day the desired amount can readily be found by observation of the pulse rate with the patient at rest and in a nonexcited state.

Occasionally we have a desperate case of heart failure with auricular fibrillation with a high ventricular rate (150-200) in which it appears desirable to reduce the rate even more rapidly. In such a case we resort to intravenous medication. In my opinion digitalis lanata preparations are best for this purpose, though one can dilute an ordinary tincture with saline solution and inject intravenously or use ampules of a well known preparation such as digalen or digifolin. Eight cat units of digitalis purpurea can be given safely at one injection to a patient weighing 150 pounds. I prefer to give 1 mg. of digitanid C\* or 1 mg. of digoxin to such a patient. Both of these are preparations of digitalis lanata. The report of the following case will illustrate how efficiently these preparations can work:

A woman aged 56, with high blood pressure and electrocardiographic evidence of coronary arteriosclerosis, suddenly had dyspnea and orthopnea with auricular fibrillation. After sticking it out for one week at home she entered the hospital, showing 3+ edema of the lower extremities and some puffiness about the eyes. Cyanosis, ascites and venous distention of the vessels of the neck were present. The apical rate was 145 and totally arrhythmic. The venous pressure at the level of the right auricle was 17 cm. of water. There were rales at both bases as high as the angle of the scapula. The liver was down 6 cm. The vital capacity was 900 cc. She was given 1.6 mg. of digitanid C shortly after the examination on admission. Two hours later the apical rate was 84, the venous pressure 8 cm. of water and the vital capacity 1,600 cc. She was given digitanid C orally, 0.8 mg. a day, under which her pulse ranged between 60 and 80 during the following week. Twenty hours after admission all rales had disappeared, cyanosis had disappeared and the dyspnea had lessened remarkably. On the second day in the hospital the fluid intake was 600 cc. and the output 2,200 cc. During the first week in the hospital the fluid output exceeded the intake by 6,200 cc. and all visible edema

had disappeared. On the fourth day the liver was back at the costal margin; on the third day the vital capacity was 2,400 cc., which was about her normal value. On the tenth day the patient was allowed up and around and showed no signs of dyspnea, nor had she any distress. No other treatment other than rest and digitalis was used.

This case illustrates not only how digitalis properly given can favorably affect auricular fibrillation complicating cardiac failure but how rapidly a digitalis preparation can accomplish the result when intravenously administered.

It cannot be denied that there are a few exceptions to the foregoing rules for administration of digitalis; occasionally digitalis seems to have no appreciable effect on conduction of the impulse from the auricles to the ventricles and therefore does not slow the ventricular rate, and a small percentage of patients show toxic symptoms before the optimal results in reducing ventricular rate can be accomplished. Not a few patients will need more than 1 cat unit to 10 pounds of body weight anchored in the body in order to produce optimal slowing of the pulse rate. Usually not more than from a 10 to 30 per cent increase is necessary to accomplish this. A very few patients will need less than the calculated optimal dose. This condition is usually found in coronary disease or in other conditions that in themselves reduce conductivity through the bundle of His. These cases often show apical rates of 100 or less before any digitalis has been given. When the apical rate is less than 110 it is well to use smaller amounts of digitalis than that previously recommended because conductivity from auricles to ventricles may already be impaired. If the rate is around 80 only 2 cat units a day should be given and the pulse should be watched from day to day until the physician is certain that the rate is not going to fall below 60. In hyperthyroidism digitalis usually fails to lower ventricular rate and its value is questionable. The administration of compound solution of iodine will usually reduce the rate somewhat. Operation should be carried out when it is thought safe, and after operation the fibrillation will disappear in more than 50 per cent of the cases. In toxic conditions associated with fever the dosage should be definitely smaller." The effect will often leave much to be desired, but according to the present state of our knowledge it seems unwise to go beyond one-half the usual dose in fevers with toxemia.

There are patients who are sensitive to digitalis and the reduction of their ventricular rate may be difficult. It is necessary to proceed with smaller doses, and it may be impossible to get the rate below 80-90. When more digitalis is given nausea, vomiting or extrasystoles may appear, and the patient who was beginning to compensate moderately may now show signs of decreasing compensation. One should give as much digitalis as the patient can stand without showing signs of nausea, vomiting or extrasystoles. Coupled beats developing during the course of digitalis treatment mean severe digitalis intoxication, and the drug must be withheld until all extrasystoles disappear. It may then be cautiously given again.

The ventricular rate should never be allowed to drop below 60. Lowering the pulse rate below 60 does not increase but rather decreases the efficiency of the cardiac

8. This is a preparation of digitalis lanata studied by Dr. M. R. Vissecher pharmacologically and now being investigated clinically in the Minneapolis General Hospital. The drug, prepared by the Sandoz Company, has not yet been released to the profession.

J.: The Effect of High Temperature on the Action and Toxicity of Digitalis, *ibid.* 15:427 (July) 1920.

pump. Signs of decompensation usually do not reappear until the rate falls to 50 or below, but 60 should be the lower limit of the pulse rate at rest.

#### QUINIDINE

Up to this point I have been discussing the treatment of auricular fibrillation in patients who had in addition a valvular disease or a diseased myocardium. There are a few patients who have attacks of auricular fibrillation unassociated with any discoverable organic heart disease. These attacks may be associated with great excitement or emotion. For example I have seen one patient who had a number of attacks of auricular fibrillation following the excitement of the sexual act. Occasionally severe physical exertion will bring on an attack. I have observed one such case in a track athlete. Attacks of auricular fibrillation may follow infectious diseases such as influenza and pneumonia. Drugs and chemicals may induce attacks. In my experience attacks of auricular fibrillation following drinking bouts are not at all uncommon. The outlook in these cases is excellent as a rule and the patient usually suffers only from palpitation, smothering, weakness, mild precordial distress or a little dizziness. Occasionally cardiac failure will develop even though there is no evidence of the presence of organic heart disease. As a rule the fibrillation is easily terminated in these cases and normal rhythm restored by the use of quinidine. As far as my reading goes all who write on this subject agree that quinidine is the drug of choice in auricular fibrillation unaccompanied by serious organic heart disease.

On the other hand there are many competent cardiologists who warn against the use of quinidine to terminate auricular fibrillation in cases of organic heart disease or who overemphasize the dangers of quinidine in the treatment of auricular fibrillation complicated by organic disease of the heart. We have used quinidine to terminate auricular fibrillation for the past seventeen years and during this period my associates and I at the Minneapolis General Hospital and at the University Heart Clinic have treated with quinidine more than 500 patients having auricular fibrillation. In approximately 65 per cent of these cases the auricular fibrillation has been stopped and the ventricular rhythm has become regular. Moreover we have prevented the return of fibrillation in nearly every patient who has continued the daily dose prescribed for prophylaxis. In general we are well satisfied with the results of quinidine therapy in our cases. Many patients who were uncomfortable and unable to carry out even moderate physical exertion on digitalis therapy alone were made easy and recovered considerable ability to carry on physical exertion after quinidine had restored normal rhythm.

That there are grave dangers inherent in the use of quinidine I do not deny. Quinidine is a drug which is toxic for the heart muscle. It reduces the strength of contraction of the heart muscle and in our early use of the drug we occasionally brought on cardiac failure while attempting to terminate auricular fibrillation.<sup>10</sup> Since then we have learned that the use of quinidine in treating auricular fibrillation in hearts that have been decompensated or that present serious organic disease must be preceded by thorough digitalization of the heart. Under these circumstances cardiac failure will not develop even when large doses of quinidine are

given. Before giving quinidine we give sufficient digitalis to bring the ventricular rate to values around 60-70. This rate is maintained by daily doses for approximately two weeks before quinidine therapy is started. If the patient was severely decompensated before digitalis therapy was started we might wait a little longer before beginning the quinidine therapy. Under these circumstances we do not fear the adverse effect of quinidine on the mechanical efficiency of the heart muscle.

Another danger that is only rarely encountered when quinidine is used is that of asystole. I myself have observed only one case:

A woman aged 36 who had rheumatic fever in her youth was seen by a local physician in an advanced stage of cardiac failure associated with mitral stenosis and auricular fibrillation and a greatly dilated heart. She was overdigitalized and during the period that her heart was showing coupled beats she was given quinidine. When 30 grains (2 Gm.) was given unconsciousness developed. Her physician observed five attacks of asystole in three hours and called me in consultation. She recovered and her heart was kept regular for three years. Auricular fibrillation reappeared and in a few months she died of multiple embolism.

It should be noted that these emboli did not develop during the period when quinidine restored and maintained regular rhythm but at a time when the auricles were fibrillating. In reviewing this case critically I would say that two mistakes were probably made. Quinidine should not be given in doses larger than 15 grains (1 Gm.) a day when there is evidence of digitalis poisoning because there may result therefrom a dangerous summation of the toxic effects of both drugs. This patient was suffering from digitalis intoxication (coupled beats) when the quinidine was administered. It would have been better to wait one week after all signs of toxicity had disappeared before starting quinidine. Moreover, this patient had a markedly dilated heart as shown by x-ray and postmortem examination. In such cases it is advisable either to withhold quinidine or to proceed more slowly in increasing the dose.

Embolism is a danger that undoubtedly is associated with the use of quinidine but one that has been overemphasized in my opinion. The paralyzed auricle is a favorite site of mural thrombi. When the auricles beat again a piece of thrombus may be dislodged and become an embolus. In my experience embolism is less frequent following the restoration of regular rhythm with quinidine than it is in cases in which only digitalis is used and in which the auricles are allowed to fibrillate. Viko, Marvin and White<sup>11</sup> have shown that embolism occurred in 4.5 per cent of their untreated cases and in 3.1 per cent of their cases treated with quinidine. Korns<sup>12</sup> questions the greater incidence of embolism in quinidine-treated cases. Parkinson and Campbell,<sup>13</sup> after a careful analysis of embolism in quinidine therapy, came to the conclusion that this danger has been overemphasized. I have not infrequently seen embolism follow resumption of fibrillation in auricles that had been kept regular for long periods on quinidine.

Cases of syncope occur rarely. I myself know of only one such case. The patient was treating himself and it was proved that he had been taking excessive doses at times. Epileptiform convulsions are also rare

episodes in patients who are abnormally sensitive to quinidine. I have observed one such case in the University Hospital. Convulsions followed a dose of only 6 grains (0.4 Gm.). The most common manifestations of sensitivity to quinidine are epigastric distress, nausea, vomiting, headache, diarrhea, ringing in the ears, palpitation and apprehension. These symptoms should lead to a lowering of the dosage and to a less rapid increase in dosage up to the point at which auricular fibrillation is stopped. Very frequently one will be successful with a less rapid increase in dosage. If these symptoms do not disappear and if they become annoying it is best to stop the quinidine altogether.

Having first stated the disadvantages of quinidine, I shall now give an account of its value in treatment. There is no question in any one's mind that quinidine is the treatment *par excellence* in auricular fibrillation not associated with serious organic heart disease and when auricular fibrillation in hyperthyroidism is still present two weeks after thyroidectomy. As a rule these cases show regular heart rate on small doses of quinidine and unpleasant episodes are very rare. Kerkhof<sup>14</sup> and others have shown that the efficiency of the heart is increased 25 per cent in mitral stenosis with auricular fibrillation when regular beating of the auricles is restored even though the heart was kept at an optimal rate by the use of digitalis during the period of fibrillation. I therefore recommend a trial of quinidine in all cases of mitral stenosis with auricular fibrillation in which the total transverse diameter of the heart is not enlarged more than 20 per cent and when the abnormal rhythm has not been present for more than six months. The physician who is experienced in the use of quinidine may extend these limits, but the beginner should stay within them. The use of quinidine must be preceded by digitalization and the heart must have been well compensated for two weeks before the quinidine therapy has been started. Digitalis must be given through the treatment with quinidine; we often continue it after the cardiac rate has become regular in cases of marked cardiac enlargement. Quinidine must be given every day after the rhythm has become regular because most hearts will revert to the absolutely irregular rate from weeks to months after the drug has been discontinued. Patients must be warned not to discontinue the drug. The average case will continue with regular rhythm on 9 grains (0.6 Gm.) a day. Occasionally we give 12 grains (0.8 Gm.) a day. Rarely we give 1 Gm. or 15 grains, a day to keep a heart regular. I have given doses of 9 and even 12 grains a day for as long as ten years and have never yet had occasion to regret it. I believe that continuance of regular rhythm in mitral stenosis will increase life expectancy materially.

Physiologists agree that the auricles contribute to the filling of the ventricles. Wiggers<sup>15</sup> states that they contribute on an average 35 per cent of the total filling, which would indicate that the auricle is an important part of the pump mechanism. If the auricles do not contract, venous pressure must rise or the cardiac output will fall even in a normal heart. Rise in venous pressure is the fundamental mechanism in bringing out the symptoms of dyspnea and edema. For this reason, and also because many patients feel much better

when the heart rate is regular, we try quinidine therapy in cases of auricular fibrillation associated with hypertensive heart disease and coronary arteriosclerosis. In these older patients quinidine seems to have no more contraindications than in the younger ones with mitral stenosis. The same rules for administration apply in these cases.

We administer quinidine in 3 grain (0.2 Gm.) tablets. One tablet is given on the first day to test the patient for intolerance to the drug. The next morning one tablet is given at 8 o'clock and another at 9. On the third day one tablet is given at 8, one at 9 and one at 10 a. m. The dosage is increased one tablet a day, all the tablets being given at 8, 9 and 10 a. m. It might even be safer to use 2 grain (0.13 Gm.) tablets and proceed in the same way but more slowly. We prescribe as high as twelve tablets, or 36 grains (2.3 Gm.), a day but I would recommend that the inexperienced physician stop at a daily dose of 24 grains (1.5 Gm.). With this dose at least 50 per cent of all cases should have regular rhythm restored. The physician should prescribe 9 grains (0.6 Gm.) a day for the purpose of maintaining the regular rhythm as long as possible. If a patient weighing 150 pounds was severely decompensated before starting the digitalis I recommend continuing with 1 cat unit a day in addition to the 9 grains of quinidine. During the treatment the patient should be in a hospital or at home with a nurse to observe the pulse and general condition until the pulse becomes regular. Many of our patients are treated at home. A visiting nurse sees the patient once a day and reports to me each evening until the pulse is regular.

The incidence of auricular flutter is much less than that of fibrillation. In this condition the auricle is beating at a rate of from 260 to 320 a minute, but as a rule there is a 2:1 heart block. In my experience auricular flutter is frequently found in hearts that present only a moderate degree of organic disease, and the patients when seen by the physician are not suffering from the severest degrees of cardiac failure despite the fact that the ventricular rate is between 130 and 160 beats a minute. Occasionally one sees a case of auricular flutter in which there is no heart block; then the ventricle is beating at a rate of 260 or over. This is a most dangerous rate and even in an otherwise normal heart cannot go on unchecked if the patient is to live. The rate of the ventricle must be reduced at once, and with very rare exceptions this can be easily brought about by the exhibition of digitalis. In the case of the very high ventricular rates in which no block is present I recommend strongly the intravenous use of a preparation of digitalis, preferably a lanata preparation, because of the rapidity with which they work when given intravenously. When a 2:1 heart block is present and the patient is not suffering critically, digitalis may be given orally or rectally in such doses that the optimal amount of 1 cat unit to 10 pounds of body weight is introduced into the body within a period of from twenty-four to thirty hours. This will usually increase the block to a 3:1 or 4:1 block. I prefer to give enough digitalis to keep the block 4:1. Very frequently the previously regular beat of the 2:1 block will become somewhat irregular after the exhibition of large doses of digitalis because the heart will slip from 4:1 block back to 3:1 block and then again into 4:1 block. A good rule is to keep the rate of the ventricle between 60 and 70 beats a minute. A main-

tenance dose of 1 cat unit or more a day should be given to the patient in order to hold this rate.

In about 90 per cent of cases the auricular flutter will change to auricular fibrillation if this state of digitalization is kept up for a week or two. Digitalis is then stopped and in about 60 per cent of the cases that have gone over to fibrillation normal rhythm returns. I have found it advisable to give quinidine in those cases in which fibrillation does not develop after digitalization and in those in which fibrillation is not followed by normal rhythm after digitalis has been removed. We give quinidine to patients with flutter according to the same rules outlined for giving quinidine to a patient with auricular fibrillation. The percentage of success in bringing about return of a normal cardiac mechanism with quinidine is no greater in flutter than in fibrillation. A certain number of patients will remain refractory, and it is necessary to continue these patients on digitalis therapy in order to block conduction from auricles to ventricles. Starr<sup>16</sup> states that acetyl- $\beta$ -methylcholine will occasionally convert auricular flutter to regular mechanism if from 30 to 50 mg. is given subcutaneously. This drug, the action of which will be discussed under paroxysmal tachycardia, can be tried for flutter when other methods fail.

#### EXTRASYSTOLES

Extrasystoles or premature beats are seen in the doctor's office as frequently as auricular fibrillation. Most of these cases do not present serious organic heart disease, and unless the extrasystoles occur more frequently than 12 a minute they do not affect the efficiency of the heart adversely. Extrasystoles not associated with organic heart disease are usually found in nervous, worried or apprehensive persons. I have occasionally seen an athlete retired from the squad for this irregularity. On reassurance and treatment he has soon gone back to successful competition. Frequently extrasystoles are associated with flatulence, the relief of which causes the premature beats to disappear. The patient usually does not suffer from symptoms of cardiac failure but is embarrassed and frightened by what he terms his heart "flopping" or "skipping a beat" or "stopping" for an instant or "palpitation" or a "funny feeling in the heart." Treatment in these cases requires first of all reassurance that the condition is not serious. Worry and undue fatigue must be removed. A change of environment is often useful. Sedatives such as bromides, barbiturates or codeine may be necessary to reduce excitability. Occasionally tobacco or coffee must be prohibited. Sometimes lying on the left side will evacuate gas from the stomach and get rid of extrasystoles. When these measures fail, quinidine either alone or with strychnine one-thirtieth grain (0.002 Gm.) three times a day will frequently abolish this irregularity. The quinidine is to be given in doses of 3 grains three times a day increasing to four times a day or even to 4 grains three times a day.

Extrasystoles are found in at least 10 per cent of all cases of coronary thrombosis. Masters<sup>17</sup> found them in 25 per cent of the Mount Sinai Hospital cases. Here they are of grave significance and quinidine must be given to prevent the appearance of ventricular tachy-

cardia, the drug being given in doses of 3 grains every two to three hours for three or four doses. If the extrasystoles disappear the drug may be repeated every six to eight hours to prevent recurrence. Digitalis predisposes to the formation of extrasystoles and ventricular tachycardia in coronary thrombosis and should not be administered unless auricular fibrillation or flutter with ventricular rate above 95 or moderately severe cardiac failure is present. When extrasystoles occur in the course of valvular disease, in the course of hypertension or in the course of coronary arteriosclerosis they may be of serious significance, especially if they occur at frequent intervals. Quinidine or quinidine and strychnine should be used to stop them, given as already outlined. As a rule, digitalis should not be given under these circumstances.

#### PAROXYSMAL TACHYCARDIA

Paroxysmal tachycardia is, after all, only a very rapid and regular series of extrasystoles, starting suddenly and ending just as suddenly. I shall first discuss the treatment of paroxysmal tachycardia of auricular and junctional origin. In some cases these attacks come on infrequently and last only a short time, and in these there is no need for treatment. If the attacks come on at frequent intervals and embarrass the patient, digitalis in my experience will often prevent them. I would recommend giving as much digitalis as was recommended for treating auricular fibrillation, attempting to get the optimal amount into the body within three days and holding on 1 cat unit a day from then on. I have had more success in preventing auricular and junctional paroxysmal tachycardia with digitalis than with quinidine. On the other hand, some cardiologists use quinidine for this purpose. In my hands it has been effective only occasionally.

An attack of paroxysmal tachycardia usually leads to much discomfort and may have serious consequences in a patient who has serious cardiac disease. It is therefore necessary to know how to treat the attack. The patient is usually recumbent when the physician arrives. An ice bag over the precordium helps psychically. I would first try pressing on the carotid sinus, as this occasionally stops an attack. One places the second and third fingers over the carotid artery at the level of the thyroid cartilage and presses the artery very firmly back against the transverse processes of the cervical vertebrae. It should be tried first on the right carotid and then on the left. If this doesn't stop the attack I try pressing on the eyeballs. Sometimes the patient can stop an attack by closing the glottis after a deep inspiration and then pressing hard. A feather, tongue depressor or other object pressed or rubbed against the posterior pharynx so as to cause vomiting will also occasionally stop an attack. Weiss and Sprague<sup>18</sup> recommend giving from 1 to 2 drachms (3.8 to 7.5 cc.) of fresh syrup of ipecac to cause nausea and vomiting. If the effect is not obtained after forty-five minutes the dose is repeated or increased a little. This method is very efficacious. Acetyl- $\beta$ -methylcholine has recently been recommended<sup>16</sup> for the treatment of paroxysmal tachycardia of auricular or junctional origin. It is probably the surest in its action of all the drugs recommended for treating attacks. There seems to be no great danger connected with its use. I have seen one case in which there was

a short period of unconsciousness following a dose which was about double the amount I recommend in this paper. The drug is a powerful stimulator of the vagus and should not be used when there is a tendency to asthma, as its injection will bring on an attack. It produces sweating, vomiting and vasodilatation and occasionally substernal pain and defecation. I would recommend trying 20 mg. of the drug in younger patients and 30 in older patients. The drug is obtained from Merck & Co. in powder form and must be dissolved in water and prepared for hypodermic use. It is very soluble and 50 mg. can be given in 1 cc. The drug is given subcutaneously and the deposit is massaged to increase the effect if necessary. I have not yet needed to supplement the drug effect with carotid sinus pressure, though Starr claims that 20 per cent of his patients needed it. The patient should be lying down, since he may faint if he is sitting up. If the attack does not stop in two or three minutes the dose is repeated. Correspondingly smaller doses should be used in children or very small adults. Large intravenous doses of digitalis will also stop attacks. Ten cc. of digifolin or digalen in ampules may be given to the patient weighing 150 pounds in one or two doses.

Paroxysmal tachycardia of ventricular origin, or ventricular tachycardia as it is usually designated, is not infrequently discovered in patients who seem to have no organic heart disease or cardiac enlargement. Because of the rapid rate (160-220) one often finds signs of failure even when there is no evidence of any other cardiac disease. I have a number of patients who come in at long intervals with attacks and moderately severe cardiac failure. When the tachycardia is stopped they return to a life of moderately strenuous activity. There are no signs of any cardiac failure as long as they take 9 grains (0.6 Gm.) of quinidine a day. They then become convinced that they will never have another attack, omit the drug and sooner or later return with tachycardia and symptoms. In one case which I saw in consultation with Dr. Scherer, it was necessary to give 85 grains (5.5 Gm.) in five hours in order to stop the tachycardia and relieve the alarming symptoms of cardiac failure which had developed in an otherwise normal heart. This patient was like many whom I have seen in that she had been having attacks for years, the attacks becoming progressively more severe, lasting longer and being associated with alarming symptoms of cardiac failure soon after she went off her daily prophylactic dose of 9 grains.

As a rule this type of tachycardia is found most frequently in patients with coronary disease and may then be a most serious factor. It is not at all infrequent in coronary thrombosis and in that case is the next step before ventricular fibrillation and death. The need for an efficacious drug is imperative and it is fortunate that quinidine is available. I have never failed to stop ventricular tachycardia with quinidine. In ventricular tachycardia it is well to give 3 grains of quinidine to test out the patient for idiosyncrasy to the drug and then give 6 grains an hour later. If the tachycardia has not stopped by the end of the hour, 6 grains may again be given. Even though the tachycardia may not have ceased at this time I would stop giving the drug and wait four hours before repeating it. It has been shown by Lewis<sup>19</sup> that the maximal effect on ventricular rate comes four hours after quini-

dine is given by mouth and most attacks of ventricular tachycardia will stop with a total of 15 grains (1 Gm.) given in this way. There is usually time enough to save the patient's life after the four hours has elapsed. I have had success with smaller doses and I have also had patients who needed much more. There is one question that will arise in the minds of readers of this paper, namely as to the use of digitalis in these cases. Digitalis increases the tendency to ventricular tachycardia in coronary thrombosis and, once the tachycardia is established, it probably increases the tendency to ventricular fibrillation. Therefore digitalis should not be given when ventricular tachycardia is present.

#### HEART BLOCK

The treatment of heart block in my experience is the least satisfactory treatment of any of the arrhythmias. Occasionally atropine in doses of  $\frac{1}{100}$  grain (0.0006 Gm.) will so far reduce the block in the bundle of His in cases of partial heart block that digitalis may be used safely in moderate dosage to increase the mechanical efficiency of the heart muscle. In total heart block digitalis may be given to increase the mechanical efficiency of the heart muscle without fear of any reduction in ventricular rate. When attacks of asystole with syncope are occurring, from 5 to 10 minims (0.32 to 0.65 cc.) of epinephrine subcutaneously given with massage of the area will prevent asystole and syncope for from one to two hours. At the time of asystole there is no blood flow, and if the asystole with syncope and convulsions lasts from thirty to sixty seconds epinephrine from 3 to 5 minims (0.2 to 0.3 cc.) must be given intracardially in the fourth left interspace just lateral to the sternal border. Ephedrine hydrochloride in capsules containing three-fourths grain (0.048 Gm.) may be given from four to six times a day to patients having daily attacks of Adams-Stokes syndrome due to asystole of the ventricles. These patients in my experience seem very tolerant to ephedrine and can be given large doses without very unpleasant side effects. I have apparently inhibited the Stokes-Adams syndrome for long periods by chronic doses of ephedrine, although it must be admitted that it fails in some cases to prevent attacks. Wherever possible an electrocardiogram should be taken because the Adams-Stokes syndrome may be due to runs of ventricular fibrillation or of frustrate extrasystoles. In this case neither epinephrine nor ephedrine should be given, for it only increases this tendency, but rather quinidine in sufficient doses to stop the runs of ventricular fibrillation or to inhibit the frustrate extrasystoles.

#### ABSTRACT OF DISCUSSION

DR. WILLIAM J. KERR, San Francisco: In the main, I agree with what Dr. Fahr has said about the treatment of disturbances in the mechanisms controlling the heart. I agree with what he said about digitalis, with one possible exception. I believe there are patients who have advanced mitral stenosis with a button-hole mitral valve who will not do well if the ventricular rate is reduced to the level which he suggests. Some of these patients, I am sure, will be better off at a rate of from 80 to 90 than at the lower figure. Dr. Fahr wisely suggests that there is no need for the extremely rapid digitalization of patients which was suggested a few years ago. If the result can be achieved in three or four days in the average person, that is the most satisfactory method. I agree with Dr. Fahr that the dangers of quinidine have been overrated, excepting in older persons who already have some degree of heart block, to whom

19. Lewis, Thomas: Value of Quinidine in Cases of Auricular Fibrillation, *Am. J. M. Sc.* 163:781 (June) 1922.

I think it should be given with great caution. I believe it is far better to give the quinidine regularly about every five or six hours around the clock in preference to single doses given early in the morning. I think that if cases are chosen properly and it is given regularly throughout the day and night the results will be much higher than 50 per cent and will approach 80 per cent in practice. Dr. Fahr did not have a chance to speak of extrasystoles, paroxysmal tachycardia, ventricular tachycardia and heart block. I should like to make one point about ventricular tachycardia which I hope he will discuss in closing. It is suggested that quinidine should be used more frequently in ventricular tachycardia. If all patients with ventricular tachycardia are given quinidine there will be real trouble because a high percentage of these patients have serious vascular disease of the heart. A good many of them have block in the conduction system and since quinidine acts on the conduction system tending to increase the block as well as on the muscle, I think the dangers of making the patient worse and producing a ventricular fibrillation are considerable in this group. While there are some reports of good results in this abnormal mechanism, I believe it is a dangerous drug to use in a routine manner under these circumstances.

DR. HORACE M. KORN, Iowa City: I wish to supplement Dr. Fahr's excellent presentation with a few remarks on the treatment of supraventricular paroxysmal tachycardia. The number of attacks may be greatly reduced by the continuous administration of quinidine sulfate in doses of from 3 to 18 grains (0.2 to 1.16 Gm.) a day. Individual attacks can be terminated by pressure over one or both carotid sinuses, pressure on the eyeballs, swallowing ice water, performing Valsalva's experiment or inducing vomiting by means of ipecac or tickling the pharynx. Attacks which are resistant to these measures may be terminated by acetyl-beta-methylcholine (mecholy). The dose is proportional to age and body weight. From 10 to 20 mg. may suffice for patients between 10 and 20 years of age, and from 40 to 50 mg. may be required for those over 50 years of age. Sixty mg. might be needed for an obese person. The average dose is 30 mg. The drug is given subcutaneously or intramuscularly, never intravenously. If the attack does not stop promptly, pressure is applied first to one, then to the other, carotid sinus. The injection may be repeated and the dose increased within ten minutes, so that if necessary as much as 100 mg. may be given in less than an hour. If the dose is too large the heart may stop beating for as long as from thirty to forty-five seconds. Before giving mecholy it is advisable to have ready a syringe containing one-fiftieth grain (0.0013 Gm.) of atropine, which is an instantaneously effective antidote, but beating will probably be resumed whether atropine is given or not, for it is impossible to keep the mammalian heart inhibited by vagus stimulation. If atropine is used it should be given intravenously. Quinidine is antagonistic to mecholy, and if the patient has taken any quinidine within twenty-four hours of the time when mecholy is given the latter may fail even if the dose employed is larger than it would ordinarily be. It has been the experience of most observers that mecholy will stop paroxysmal supraventricular tachycardia in from 80 to 90 per cent of the cases, especially when it is used in conjunction with carotid sinus pressure. The danger is practically negligible, provided cases of asthma, angina pectoris and far advanced myocardial disease are excluded. The introduction of mecholy means that at last a brilliantly successful remedy has been found for what is often an extremely intractable and serious disorder of the heart beat.

DR. S. A. WEISMAN, Minneapolis: I might add a few words about the treatment of auricular fibrillations with quinidine. As Dr. Fahr stated, it is important first to digitalize the patient and get the heart rate down to between 80 and 70. It is perhaps wise to cut down the digitalis to a maintenance dose before the quinidine is begun. I prefer to use a smaller beginning dose than Dr. Fahr does, because I believe that with this smaller dose the patient is more apt to establish a tolerance for the drug and not experience the toxic symptoms one so often reads about. I begin usually with 0.1 Gm. the first day, 0.2 Gm. the second, 0.3 Gm. the third and 0.4 Gm. the fourth day, given in doses of 0.1 Gm. each, one hour apart. Then begin, say, the fifth or sixth day with 0.2 Gm. every hour for three doses. The next day give 0.2 Gm. for four doses, making a total of

0.8 Gm. daily. From this point I usually give 5 grains (0.3 Gm.) every hour for three doses, then in a few days give 5 grains every hour for four doses, then after a few more days 5 grains in the first dose, then 10 grains (0.65 Gm.) in the second and 10 grains in the third. The final dose I use is 10 grains every hour for three doses. I usually quit at about 30 grains (2 Gm.) a day if the heart has not returned to normal rhythm, to which some 70 per cent have usually returned by that time. After the normal rhythm is once established, I begin to cut down the doses by 5 grains every two or three days until a maintenance dose is established. Then I continue giving, say, 10 grains or, in some cases, 5 grains, a day for years but always keep the patient on a maintenance dose of digitalis together with a maintenance dose of quinidine. The mitral stenosis group seems to be the most difficult to restore to regular rhythm. These cases are the most difficult to maintain regularity and are also the ones that are most apt to return to arrhythmia. The hypertension and coronary sclerosis groups react much more favorably to this treatment.

DR. WILLIAM DRESSLER, Berkeley Calif.: I should like to mention a remedy which I have used in Vienna, Austria for paroxysmal tachycardia. It is magnesium sulfate, which I use intravenously in doses of 15 cc. in 20 per cent solution, and I have had in many cases an excellent result. The effect appears in about five minutes, sometimes a little sooner. The injection is performed rather quickly, particularly in ventricular paroxysmal tachycardia after coronary occlusion. It has proved very successful, in some cases really life saving. I have never seen any unfavorable effect.

DR. GEORGE E. FAHR, Minneapolis: Those who have discussed my paper have helped greatly in attempting to cover the treatment of cardiac irregularities in fifteen minutes. Dr. Kerr has stated that when he has one of those narrow buttonhole mitral stenoses it is better to hold the rate around 80-90 rather than around 60-70. I agree if he means patients with markedly dilated heart who have been decompensated for a long time and who show ventricular extrasystoles or coupled beats when the slowing of the heart gets down below 80-90 beats per second. Signs of digitalis intoxication are always indications for less digitalis. I am surprised that Dr. Kerr can get normal rhythm with the use of quinidine in 80 per cent of his fibrillators. I have never been able to get more than 65 per cent. In cases of arteriosclerotic heart disease I am able to get a percentage up around 80 but in mitral stenosis I have great difficulty in getting more than 65 per cent to become regular. It is possible that Dr. Kerr's method of administering quinidine is better than mine. I shall try it. I am surprised about what Dr. Kerr said as to the use of quinidine in ventricular tachycardia. I have always used it in treating cases of ventricular tachycardia. In my opinion it is especially indicated when ventricular tachycardia follows a coronary thrombosis. Ventricular tachycardia is the next step on the way to ventricular fibrillation. I believe it is necessary to give quinidine to stop the ventricular tachycardia and prevent ventricular fibrillation. I have given as high as 85 grains (5.5 Gm.) of quinidine in a twenty-four hour period because I believe it is absolutely necessary to stop the tachycardia. I am grateful to Dr. Korn for discussing the use of acetyl-beta-methyl choline, or mecholy, in the treatment of paroxysmal tachycardia of supraventricular origin. As far as my experience goes I have been 100 per cent successful in stopping paroxysmal tachycardia of supraventricular origin with this drug. I believe Dr. Weisman's method of starting off with smaller doses and increasing the amount of quinidine more slowly is probably safer than my own. Dr. Weisman carries out the treatment of auricular fibrillation by his method in the ambulatory cases in his private practice in Minneapolis. He has told me that he has never had to regret the use of quinidine in that practice. I would disagree with one thing in his method: when he gets up to a fairly large daily dose, he then proceeds as fast as I do. That would be the point at which I would go more slowly. Dr. Dressler has suggested a new remedial agent for the treatment of paroxysmal ventricular tachycardia and I shall be delighted to try it out. No one need fear the use of intravenous magnesium sulfate if there is a hypodermic of calcium chloride handy on the tray in case there is trouble with the respiratory center.

## PATHOLOGY OF THE PLACENTA

WITH SPECIAL REFERENCE TO INFARCTS AND THEIR  
RELATION TO TOXEMIA OF PREGNANCY

R. A. BARTHOLOMEW, M.D.

ATLANTA, GA.

The pathology of the placenta may be better understood and appreciated if approached from the standpoint of the life cycle of this organ and the influences to which it is subjected from the time of implantation to full term. Accordingly, certain fundamental basic facts will be considered and the pathologic changes which may arise from each of these will be discussed.

Since this article deals particularly with placental infarction, no attempt will be made to consider in more than a brief way the various other pathologic conditions, which are fully discussed in the textbooks and literature.

Embryologically, the anlage of the placenta is trophoblastic tissue, one of the primary germ layers. As such it is endowed with peculiar invasive qualities by virtue of its proteolytic enzymes, whereby it is able to attach itself to the uterine decidua, embed in it, open maternal blood vessels and create for itself a vascular bed. Potentially therefore one would expect an aberrant growth of such tissue, especially in the period of its greatest activity, the early months of pregnancy, to be highly malignant and destructive.

Chorio-epithelioma may thus arise if trophoblastic tissue takes on a malignant change. Marchand demonstrated the origin to be in the syncytium and Langhans layer of the villi. The growth may simulate villous structure, or it may be quite atypical in arrangement of the cells. While it may develop in association with early normal pregnancy or abortion, it is particularly liable to appear in association with or following hydatidiform mole. In many cases there is an interval of months or even years between the pregnancy and the appearance of the growth.

On account of the destructive and vascular character of the growth, uterine hemorrhage is an early symptom. Metastases occur through the venous channels and appear particularly in the vagina, vulva and lungs. X-ray examination of the chest may reveal pulmonary metastases. The Aschheim-Zondek test shows an unusually high concentration of the hormone and is of great value in diagnosis and prognosis. Unfortunately the clinical course of the growth is more conclusive proof of its malignant tendency than the microscopic examination, as spontaneous disappearance of the growth has been observed.

Accompanying the penetration of trophoblastic buds into the uterine decidua at a very early stage, vascularization of the future villi is effected through further differentiation of the trophoblastic layer, until the future placental area develops a rich circulation. Potentially therefore, in a tissue which is so highly vascularized, excessive capillary growth may occur, even to the extent of tumor formation. In this manner angioma of the placenta may arise.

In sectioning fixed placentas in strips from 0.5 to 1 cm. thick, I have found the characteristic firm, round

or oval encapsulated angioma only twice in examining about 2,000 specimens. While angiomas do not usually exceed from 1 to 2 cm. in diameter, much larger ones have been reported. The tumor may be shelled out of its pseudocapsule very much like a fibroid tumor of the uterus. Microscopically it is made up of innumerable small crowded capillaries, apparently within the confines of the stretched out Langhans and syncytial boundary of the original villus. Angioma is of no significance unless large enough to induce premature labor or possibly cause dystocia.

Conversely, if the villi fail to be vascularized or are insufficiently vascularized, degenerative changes of a hydropic nature may occur in the stroma and the lining cells which may possibly account for hydatidiform mole. One observes a similar tendency to edema of the villi, with the failing vascularity incident to syphilis of the placenta. In hydatidiform mole, however, the process is not a simple edema affecting the villous stem uniformly throughout but is a hydropic degeneration localized in a succession of enlargements along the course of the stem, giving rise to grapelike clusters of thin-walled cysts, which add immensely to the size and weight of the placenta and tend to loosen it from the uterine wall.

Embryonic growth is interfered with at a very early stage, and one seldom finds any trace of embryo or normal placental tissue. The Aschheim-Zondek test is strongly positive, because of increased concentration of the hormone. Enlargement of the ovaries, due to lutein cyst formation, frequently occurs and may be due to overstimulation of the anterior lobe of the pituitary gland from the excessive growth and degeneration of the epithelial elements of the villi. The enlargement subsides rapidly after expulsion of the mole.

The site of attachment and embedding of the fertilized ovum determines the location of the placenta in the uterus. While this is apparently largely a matter of chance, the vast majority of implantations are on the anterior or posterior wall of the fundus or body of the uterus.

Implantation in the lower uterine segment, resulting in placenta praevia, occurs much more frequently in multiparas. Is it not possible that the explanation of this lies in the fact that the anterior and posterior walls of the parous uterus are separated more than those of the virgin uterus, thus permitting the blastocyst to gravitate to a low level before embedding?

It would be of interest to compare the incidence of placenta praevia in a large series of cases in which the uterus is known to have been retroverted early in pregnancy with that in a like number of cases in which the uterus is known to have been in normal anteversion early in pregnancy.

Variations from the usual oval or round shape of the placenta probably result from lateral or cornual implantation. It is possible, however, that persistence of chorionic villi which unexpectedly survive their unfavorable location over the chorion laeve may account for some of the irregularly shaped placentas or the islands of placental tissue sometimes seen on the membranes and termed placenta membranacea.

During the second and third trimesters of pregnancy, with increasingly frequent and strong Braxton Hicks contractions and trauma, both from fetal movements within the uterus and stimuli from without, some of the outermost fastening villi at the margin of the placenta are probably torn from their decidual bed, thus

From the Department of Obstetrics, Emory University School of Medicine.

Read before the Section on Pathology and Physiology at the Eighty-Ninth Annual Session of the American Medical Association, San Francisco, June 15, 1938.

causing repeated slight extravasations of blood at the margin of the placenta. The blood is prevented from extending inward beneath the placenta by the denser, more secure fastening villi or outward by the adherence of the membranes to the uterine wall. Consequently it follows the path of least resistance and bulges the chorion and amnion inward over the fetal surface of the placenta. This bulging fold of chorion and amnion, with its contained blood, is gradually flattened down onto the margin of the placenta by the intra-amniotic pressure.

After absorption of the hemoglobin the remaining fibrin creates the appearance of a thickened yellow border around part or all of the circumference of the placenta. This is, according to my observations, the probable mode of origin of circumvallate placenta. A section through the margin of such a placenta should show, from without in, (1) placenta, (2) chorion, (3) amnion, (4) amnion, (5) chorion, (6) fibrin, (7) chorion and (8) amnion. It is difficult, however, to identify and trace each of these layers in a specimen. The circumvallate border apparently opposes the further outward course of the vessels on the fetal surface of the placenta; these are seen to dip into the substance of the placenta at the inner margin of the circumvallate ring and continue their course within the placental substance to the extreme rim of the placenta, which in some cases extends several centimeters beyond the circumvallate ring.

In the last half of pregnancy certain changes occur in the placental arteries which play an increasingly important part, predisposing to hemorrhage and infarction. The basis for the vascular changes is the hypercholesteremia of pregnancy, which, from the early months on to term, is probably of fundamental importance to fetal growth.

Cholesterol, in the language of the biochemist, has been termed the framework of the body cell. If it is, there must be some mechanism by which the maternal organism mobilizes cholesterol to supply the excessive demands of cell growth in the fetus. It is thought that the pituitary gland governs cholesterol metabolism, and stimulation of the various functions of this gland by pregnancy may explain the mechanism by which the value for blood cholesterol increases from a normal one of from 150 to 170 mg. to an excessive one of from 200 to 250 mg. or more per hundred cubic centimeters. This value is still further increased if there is associated hypothyroidism or if the diet is particularly rich in cholesterol-containing foods.

Another factor, which, independently and also in conjunction with the hypercholesteremia of pregnancy, lays the basis for vascular changes in the placental arteries, is trauma produced by the increasingly vigorous movements of the fetal extremities on the unprotected vessels on the fetal surface of the placenta in the latter part of pregnancy. In respect to vulnerability, lack of support from surrounding tissue and subjection to direct trauma, the placental circulation is unique and unlike that of any other part of the body.

Under the combined influence of hypercholesteremia and fetal trauma, focal collections of lipid-like cells arise beneath the endothelium in some of the smaller placental arteries, probably at points where the vessel has been traumatized. I<sup>1</sup> noted the similarity in appear-

ance of these focal accumulations of lipid-like cells in the smaller placental arteries to the experimental cholesterol-induced vascular changes in rabbits and the spontaneously occurring vascular change accompanying coronary thrombosis in man, as shown by Leary.<sup>2</sup>

The accumulation of lipid cells beneath the endothelium and in the vessel wall may disturb the circulation in either of two ways. The lumen of the vessel may be gradually narrowed by bulging of the focus of lipid cells, which may finally shut off the circulation to the dependent villi, or the endothelium overlying the lipid cells may break down, either spontaneously or from the trauma of fetal movements, thus causing sudden thrombosis and loss of blood supply to the villi. Infarction necessarily follows, progressing rapidly in case of thrombosis or more slowly in case of mere narrowing of the lumen.

Areas of acute infarction in the placenta and their association with toxemia of pregnancy were first emphasized by Young.<sup>3</sup> He, however, considered them to be the result of interruption in the maternal blood supply, a view which cannot be reconciled with the sinusoidal character of the intervillous circulation. Manifestly, loss of maternal blood supply to any part of the placental site cannot deprive adjacent villi of maternal blood, which is free to reach this area from the surrounding intervillous circulation. Furthermore, villous vessels in the infarcted area are found to be thrombosed, indicating that the cause is on the fetal rather than the maternal side of the circulation.

Placental infarcts have been attributed also to the effect of some unknown toxic substance in the maternal circulation which causes localized degeneration of the villi. In view of the sharp line of demarcation between necrotic villi within the infarcted area and the surrounding healthy villi just beyond the border of the infarct, and the open intervillous circulation common to the two areas, it is inconceivable that any maternal poison circulating freely throughout the intervillous spaces would show a selective action on certain areas and not be uniformly harmful to all villi.

Failure to appreciate the relationship between placental infarcts and toxemia of pregnancy has been due to improper preparation and examination of the placenta and lack of familiarity with the more acute types of placental infarcts. The placenta should be wiped free of blood, the membranes cut away from the margin and the specimen fixed in 10 per cent solution of formaldehyde for from three to four weeks. It should then be cut in strips from 0.5 to 1 cm. thick, which are closely examined for evidence of infarction or hemorrhage.

Previous to 1937 I followed a routine of examining placentas in the light of a knowledge of the clinical history of each case. One cannot avoid being influenced in his interpretation of a suspicious area if he knows in advance whether or not the patient has had toxemia. During the past year all examinations have been made on "unknown" placentas, without a knowledge of the patient's clinical history at the time the placenta was sectioned. A definite diagnosis as to the occurrence of toxemia during the pregnancy has been made on the basis of the gross pathologic changes and then compared with the clinical diagnosis.

By this method it has been possible to arrive at a much more accurate classification of placental lesions and establish criteria and characteristics which differentiate the acute from the subacute or more chronic types. In a recent publication<sup>4</sup> placental infarcts were classified as A, B, C, D and E, listed in the order of increasing rapidity of infarction as well as in the order of increasing toxicity. The italicized letters indicate the infarcts which are associated with the increasing degrees of toxemia.

If infarction occurs rapidly the affected placental tissue appears as one or more round or oval areas

Fig. 1.—Placental strips from a primigravida, aged 21, who was normal at the twenty-seventh week of pregnancy but showed edema, slight albuminuria and a blood pressure of 150/82 at the thirtieth week, with no apparent increase at the thirty-second week. Two weeks later eclampsia and abruptio placentae developed; the blood pressure was 152/108 and increased to 170/130, and there was heavy albuminuria. Pregnancy was terminated and the patient recovered. Diagnosis from this placenta, sent from Dr. N. J. Eastman's service, Johns Hopkins Hospital, and examined as an "unknown," was as follows: Infarct C (1) and B (2) were probably responsible for a gradually increasing toxemia of several weeks' duration, followed by an acute exacerbation with severe toxemia and abruptio placentae due to early D (3), late D (4) and early E (5) infarcts. A late D infarct (4), with a superimposed blood clot, was responsible for the abruptio placentae. Infarct A (6) is nontoxic.

from 1 to several centimeters in diameter, which are sharply demarcated from the surrounding normal placental tissue by the color, which is a dark purple-black. These areas correspond to the distribution of the obstructed vessel. The consistency is still spongy and soft, as in normal placental tissue. When the strip is held toward the light the infarcted area preserves a granular-appearing surface. When the strip is bent the infarcted area bends as easily as the normal tissue. There may be a soft or a firm clot within or adjacent to the area. This type of infarct is designated as the early E infarct (figs. 1 and 2).

Microscopically, the stroma and lining cells of the villi show pyknosis and early karyolysis and are somewhat swollen, because of congestion of the villous capillaries. Many villous capillaries are thrombosed or show marked distention and rupture, with extravasation of fetal blood into the intervillous spaces, which accounts for the soft or firm clot. The intervillous circulation is freely open, there being no evidence of thrombosis.

Biochemically, placental tissue has been found to contain relatively more arginine than any other tissue.<sup>5</sup> Theoretically, in the process of autolysis of the infarcted area, guanidine may result from the breaking down of arginine<sup>6</sup> and, since guanidine is known to produce convulsions, the peculiar eclamptogenic nature of placental autolysate may thus be explained. Kracke, in testing the effects of injection of autolysates of various

tissues into animals to stimulate leukocytosis, has never observed convulsions, although toxic effects are evident.

Other poisonous protein split products resulting from placental autolysis are probably peptone and histamine. Peptone, if present in sufficient concentration, inhibits thrombosis through its anticoagulant effect. This tends to keep the intervillous circulation open and permits absorption of the poisons into the maternal circulation. The known effects of these products explain practically all the clinical and pathologic manifestations of toxemia of pregnancy.

Clinically, the acute type of infarction is associated with the more acute, fulminating, preeclamptic, eclamptic or abruptio placentae type of toxemia, and there is a direct relation between the amount of tissue involved and the severity of the toxemia. It is usually found when the patient progresses from a normal state to preeclampsia, eclampsia or abruptio placentae within a week or ten days.

If infarction is slightly older or less acute (late E infarct, fig. 2) the lesion is still dark or purple-black but has changed from a spongy to a more compact firm area, sharply demarcated from the surrounding lighter spongy tissue. It is firmer to palpation, and when the strip is held toward the light the surface of the lesion appears marble-like and shiny. When the strip is bent, the infarcted area either cracks sharply or holds together and does not bend with the rest of the strip.

Microscopically, the villi show pyknosis and some degree of karyolysis and karyorrhexis. Some of the distended villous capillaries are ruptured and the extravasated blood, with tissue debris, fuses the villi and causes the area to appear more compact. There is still open intervillous circulation, which disseminates poisonous protein split products of placental autolysis. Clinically, the toxemia is almost if not quite as fulminating as that associated with the early E infarct, but there may be opportunity to induce labor before abruptio placentae or eclampsia occurs.

If infarction is still less acute or of longer duration, corresponding to a clinical course of from two to three

Fig. 2.—Placental strips 3 and 4 were obtained from patients with eclampsia and preeclampsia, respectively. The arrows point to two late E infarcts (1) and early E infarcts (2, 3, 4 and 5).

weeks, the infarcts vary from a faint brown (early D) to a definite brown (late D), as seen in figure 1, and are sharply demarcated, firm, compact, smooth and shiny and hold together when the strip is bent. Microscopically, the blood cells, both maternal and fetal, are more degenerated and stain more faintly, the change in the hemoglobin accounting for the brown color. The villi show more necrosis and disintegration. The inter-

4. Bartholomew, R. A., and Colvin, E. D.: Tr. Am. Gynec. Soc., June 1938; Am. J. Obst. & Gynec. 36: 909 (Dec.) 1938.

6. Bartholomew, R. A., and Parker, Francis: Am. J. Obst. & Gynec. 27: 72 (Jan.) 1934.

villous spaces are still open and permit free absorption of toxic autolytic products.

In a series of 100 placentas, from both normal and toxic patients, examined as "unknowns,"<sup>4</sup> there were twenty which suggested severe toxemia, classified clinically as preeclampsia, eclampsia and abruptio placentae. The presence of early and late types of infarcts *D* and *E* made it possible to make a correct pathologic diagnosis in 90 per cent of the cases.

If infarction is even slower the lesion, designated as infarct *C* (fig. 1), appears as a brown-yellow, sharply demarcated area and may show some softening or breaking down. Microscopically, the villi stain poorly or not at all and show considerable disintegration. The intervillous circulation is sufficiently open to permit absorption of toxic products, but there is considerable intervillous thrombosis in some parts of the infarct. Clinically, infarct *C* is associated with toxemia of a more gradual but progressive type, extending over a period of four or five weeks. Induction of labor may be necessary.

Infarct *B* (fig. 1) is a slow-forming, yellow-white, firm, sharply demarcated lesion and is apparently due to gradual obliterative endarteritis or slow occlusion from cholesterol-induced vascular change. Since the small arteries are more often affected, the infarct is usually found on the margin of the placenta.

Microscopically, the villi are pale and stain faintly but preserve their normal outline. There is no disintegration. The thrombosed intervillous blood has been changed to a dense homogeneous pink-staining hyaline substance, but in some areas there is still slight intervillous circulation. The yellow color of the lesion is due to scattered areas of incomplete thrombosis, containing shadows of degenerated red cells and some active necrosis of the villi, which permit slight absorption of toxic products.

Clinically, infarct *B* is associated with very mild manifestations of toxemia. The patient may have had slight edema, a trace of albumin and a slight rise in diastolic blood pressure, to 80 or 85, but there has been no tendency to increased toxemia unless a new area of more acute infarction occurred.

Infarct *A* (fig. 1) is firm and sharply demarcated and appears identical with infarct *B* (fig. 1) except that it is white. The absence of yellow color is due to complete hyalinization of the intervillous blood which surrounds the pale "ghost villi." Since the etiologic factor is slow obliterative endarteritis in a terminal artery, infarct *A* is usually on the margin of the placenta. It is nontoxic, not only because of the complete hyalinization of the intervillous blood but also because of the slow necrosis of the affected villi.

Lesions *A*, *B*, *C*, *D* and *E* are true infarcts characterized by progressive increase in the rapidity of infarction. Grossly, the more rapid the infarction the less conspicuous the lesion, the less firm the consistency, the darker the color and the greater the toxicity. Microscopically, the more rapid the infarction the less apparent the intervillous thrombosis and, except in the most acute stage, the greater the disintegration and loss of staining power of the villi. The range in color, due to change in the hemoglobin, is from very dark purple-black in infarct *E* to brown in *D*, to brown-yellow in *C*, to yellow-white in *B* and to white in *A*. The size and number of the infarcts bear a definite relation to the severity of the toxemia.

Simple hemorrhage without associated infarction may also occur in the placental substance. Since there can be no hemorrhage in a sinusoidal circulation such as the intervillous circulation, the probable source of such hemorrhage, when there is no associated infarction, is simple rupture of the capillaries of a terminal villus, resulting in extravasation of fetal blood. The villi are forcibly pushed aside and compressed about the margin of the hemorrhage.

Whether the collection of blood is absorbed and drained away completely, leaving an excavated open area, or whether a blood clot remains and passes through the stages from dark to brown clot and finally to white or yellow fibrin probably depends on the compatibility of the maternal and fetal blood. A slight degree of incompatibility may account for the soft transparent gelatinous areas which are occasionally seen in the placental substance. Shadows of red cells or a slight pink color give evidence of a hemorrhagic origin of these areas.

A layer of compressed villi about a recent hemorrhage may simulate an acute infarction, particularly if there is some infiltration of dark blood into the villi beyond the hemorrhage, thereby giving to the area a dark color. The lesion, however, is diffuse and not sharply demarcated. Microscopically, the villi do not show necrosis. If the clot is yellow or white the evident age of the hemorrhage argues against an associated acute infarction and the compressed border of the lesion is of a lighter color owing to crowded villi and diminished intervillous blood.

The cause of simple hemorrhage in the placental substance is obscure, but it seems reasonable to believe that temporary pressure on the thin-walled umbilical vein through certain movements or positions of the fetus in the late months of pregnancy may cause sufficient distention of a terminal villous capillary that rupture may occur.

Small collections of yellow-white fibrin varying from 0.5 to several centimeters in diameter are frequently seen on the fetal surface of the placenta beneath the chorion. The origin of these lesions is undoubtedly rupture of small branches of the umbilical arteries from the trauma of fetal movements. They are occasionally of immense size, indicating sudden extravasation from rupture of a large artery.<sup>7</sup> Cysts on the fetal surface of the placenta undoubtedly arise from liquefaction of a localized hemorrhage.

The circulatory disturbances thus far described concern pathologic changes in the placental arteries. I believe that the rare fetal anomaly termed general edema of the fetus, concerning which Ballantine wrote a monograph, is due to occlusion of the umbilical vein at some point between its origin at the placental end of the cord and its tributaries in the liver within the body of the fetus. The condition is associated with a high incidence of toxemia and marked increase in size of the placenta, which appears pale, white and extremely edematous. The villi show marked edema and early degenerative change due to slowing or arrest of the circulation. Since the entire placenta is involved, the toxemia is acute and severe. There is urgent need to investigate cases of general edema of the fetus, particularly from the standpoint of this probable etiologic factor. The frequency of fetal blood dyscrasia, with

7. Bartholomew, R. A., and Kracke, R. R.: *Am. J. Obst. & Gynec.* 24: 797 (Dec.) 1932.

excessive numbers of megaloblasts, emphasizes the importance of a complete study of the blood.

Finally, local or general infection of the placenta may occur by way of the genital tract or through the maternal blood stream. Pyogenic infection is practically always postabortal and ascending by way of the genital tract. Portions of the decidua and the adjacent intervillous spaces show thrombosis and numerous polymorphonuclear leukocytes. Invasion of the fetal circulation by the organisms, and intra-uterine fetal death, while apparently rare, may prove to be more frequent than suspected with closer study of the placenta and improved methods of isolation of bacteria from the fetus.

Tuberculous infection of the fetus is necessarily transplacental and is generally believed to be preceded by definite tuberculous lesions of the placenta. The demonstration of tubercle bacilli may require thorough search by histologic and inoculation methods. However, the finding of tuberculous lesions in the placenta does not invariably mean that the fetus is infected.

Syphilis of the placenta, contrary to statements frequently made in the literature and textbooks, is not recognizable by a specific appearance of the gross specimen and is not always suggested by undue size of the placenta. Microscopically, in the more mature placentas of the last trimester of pregnancy the villi appear large, somewhat crowded and edematous. The stroma shows rather loose open structure, and the vessels of the villi are inconspicuous in number and size and show round cell infiltration. Spirochetes are demonstrated with much more difficulty in the placenta than in the fetus. A positive histologic appearance is strong evidence of syphilis but is not regarded as positive proof.

Since the placenta apparently functions as a rather efficient barrier to transplacental infection of the fetus, some experiments were carried out by Kracke to determine if possible whether placental extract, in comparison with other tissue extracts, possesses some bactericidal power or inhibiting influence on bacterial growth when used as a culture medium. Contrary to the anticipated result, it was found to be a good culture medium for the commonly occurring bacteria and an excellent medium for streptococci.

#### CONCLUSIONS

1. Infarction of the placenta is the most important pathologic condition to which this organ is subject, not only from the standpoint of frequency but also because of its relation to toxemia of pregnancy and maternal and fetal mortality.

2. The predisposing causes of placental infarction are, first, the hypercholesteremia of pregnancy, which favors the accumulation of lipid cells at points of stress or injury of the placental arteries, similar to that seen with coronary occlusion, and, secondly, the trauma of fetal movements, which not only tends to cause deposits of lipid cells at points of injury to the placental arteries but also may break the endothelium over such a deposit or actually bring about rupture of the vessel, thus causing rapid thrombosis.

3. Toxemia of pregnancy probably results from the absorption of poisonous protein split products of placental autolysis.

4. The poisonous products of placental autolysis are probably peptone, histamine and guanidine. The patho-

logic effects of these poisons satisfactorily explain the symptoms and pathologic changes of toxemia of pregnancy.

5. The peculiar eclamptogenic character of placental autolysate is probably explained by the higher content of arginine in placental tissue, from which guanidine may be obtained.

6. Toxemia of pregnancy is associated with definite types of acute infarction of the placenta. In examining "unknown" placentas it is possible to diagnose pre-eclampsia, eclampsia or abruptio placentae in 90 per cent of the cases.

1259 Clifton Road N.E.

#### ABSTRACT OF DISCUSSION

DR. A. J. CARLSON, Chicago: I presume these placentas were taken in a routine manner. Did you examine all the placentas?

DR. BARTHOLOMEW: That is right.

DR. CARLSON: What is the amount of guanidine in the urine in these patients? There have to be considerable amounts in the blood to get these symptoms. What about the pathologic conditions in the liver that have been described in these eclamptic patients? Do you describe them as secondary effects of these poisons from the placenta?

DR. FRANK W. HARTMAN, Detroit: I had the privilege a few years ago of reviewing a thousand consecutive placentas at our hospital, and we found over 50 per cent of infarcts. We were unable to correlate in any way the number or size or occurrence of these infarcts with toxemias in this group of cases. I wonder if the infarcts in the placenta aren't the result of the same thing that produces the liver lesions and other lesions throughout the body rather than that the infarcts produce the chemical changes that are the initial cause. There is some substance which produces the spasm, perhaps, of the vessels, and the infarcts in the placenta, and the hypertension and the changes in the liver. It has been shown that one of the best ways to reproduce these lesions in the liver is to place animals under partial oxygen tension for several days, and under those conditions of anoxia the liver does show lesions very close to the lesions seen in the toxemia of pregnancy. Another condition in which similar facts have been blamed for shock and death is extensive burns. There the blood pressure goes in the opposite direction, it usually falls, and the patient dies from vascular collapse and shock. They frequently show lesions in the liver which are very similar to what are seen in eclampsia.

DR. R. A. BARTHOLOMEW, Atlanta, Ga.: With regard to whether guanidine is present in the urine, we have not finished some work that has recently been undertaken, namely, taking an equal weight of placenta and liver or spleen, and subjecting both tissues to autolysis to determine if possible whether there is a greater amount of guanidine obtainable from placental tissue. Major, I believe, has demonstrated an increased amount of guanidine in the urine of eclamptic patients and Titus has produced convulsions and eclamptic-like lesions in the liver and kidney of rabbits by injections of guanidine. In the early part of the work guinea pigs were injected with autolysate of human placenta which had autolyzed as little as four or five hours, and daily injections over a period of eight or ten days resulted in the production of typical eclamptic convulsions and a pathologic condition of the liver and kidney similar to that seen in eclampsia. I emphasized particularly that acute placental infarcts are sharply circumscribed and that the intervillous circulation in the infarcted area is widely open, permitting maternal blood which circulates freely in the adjoining healthy placenta to circulate between the necrotic villi of the infarcted area. The acute infarcts cannot be explained on the basis of a hypothetic poison in the maternal blood. Such a poison would have a uniformly lethal effect on all villi and not a selective effect in certain areas of the placenta. This, in my opinion, indicates that the infarct and its poisons are primary in the placental tissue and not in the mother's blood.

THE USE OF POTASSIUM SALTS  
IN HAY FEVER

PRELIMINARY REPORT

BENSON BLOOM, M.D.  
TUCSON, ARIZ.

The present study was stimulated by the thought that allergy is, in great part, a disturbance of electrolyte metabolism. Analogy could be drawn between demonstrated electrolyte disturbances in other diseases, such as thyroid disease (iodide), parathyroid disease (calcium), Addison's disease (sodium and potassium) and the potassium alterations that have been described in diabetes.

Cook and Stoesser<sup>1</sup> treated asthmatic children with "salt-free" diets and injections of pitressin and found that, in spite of the antidiuretic action of the pitressin, there was an increased, rather than a decreased, excretion of the sodium ion and that with this there was a distinct relief of the asthma. In one patient asthma was seemingly reinduced by the administration of a large dose of sodium chloride. This experimental work also suggests the importance of the water balance in asthma, comparable to its importance<sup>2</sup> in Addison's disease. Clinically, Piness<sup>3</sup> has stressed the importance of the need for water by patients with status asthmaticus, and he therefore administers it by various routes in copious amounts in these cases. Davis<sup>4</sup> has had remarkable success in the treatment of chronic asthma by a regimen an important part of which is the free use of water enemas.

In the article by Rusk and Kenamore<sup>5</sup> the excellent suggestion was made that urticaria might be an expression of localized edema which might respond to the action of a diuretic. They used potassium chloride and found it thoroughly effective in six cases of severe urticaria. They quote Nathan and Stern<sup>6</sup> as saying that in the acute dermatoses serum potassium fell to a subnormal level and returned to normal as the cutaneous lesions improved.

It has been demonstrated that the pharmacologic action of potassium chloride is, in many respects, similar to that of epinephrine. Seager,<sup>7</sup> however, could not verify this similarity in the iris of the frog. In addition, in my own experiences with potassium chloride none of the usual side-effects of epinephrine or ephedrine were observed in the doses used (the highest dose being 50 grains [3.2 Gm.] in twenty-four hours), in spite of its effectiveness and at times surprisingly rapid action. Rusk and Kenamore state that "effects attributed to epinephrine are actually the effects produced by potassium migration which epinephrine causes." This would readily explain the well known ineffectiveness of epinephrine in status asthmaticus after repeated, frequent

doses have been given. In other words, epinephrine liberates potassium from the tissues, and when the tissues are sufficiently depleted epinephrine can no longer relieve the symptoms of allergy.

CLINICAL RESULTS

This preliminary report deals mainly with the use of potassium salts in a number of patients with hay fever. The clinical results shown in the accompanying table appear to be so conclusive that lengthy, detailed reports of cases will be omitted.

The method of administration proved to be simple. In one of the first cases in which potassium chloride was tried it was given as a 10 grain (0.65 Gm.), enteric coated capsule. This produced agonizing epigastric pain five minutes after administration and later, when it was found that other patients complained of vague

\* Most of these patients were originally treated with 5 grains of potassium chloride three times a day; in a few cases four doses were given; the most that one patient received was 50 grains (3.2 Gm.) a day. The doses for children and the elderly must be worked out.  
† These patients had had nearly adequate relief from desensitization.

abdominal distress, it was decided to give it in 5 grain (0.32 Gm.) doses dissolved in a glass of water. This illustrates the need for extensive studies on the toxicity of potassium salts, although the latter procedure proved to be entirely satisfactory. Later, when it was felt necessary to prove that the clinical effect came not from potassium chloride as such but from the potassium ion, a mixture of potassium salts in solution was prescribed, and this was found to be almost equally effective. This solution of potassium salts contained 3½ grains (0.2 Gm.) each to the drachm (4 Gm.) of potassium acetate, potassium bicarbonate and potassium citrate. Rusk and Kenamore experienced no real difficulty with the use of 15 grain enteric coated capsules, but in view of my experience I would recommend that these salts be given in dilute solution. A 5 grain powder of potassium chloride dissolved in a glass of water is practically tasteless.

*Hay Fever.*—Altogether twenty-nine cases of hay fever, six with pollen asthma, were studied during the Tucson fall hay fever season, the common offenders at that time being false ragweed, careless weed (amaranth) and bermuda grass. The symptoms varied in severity from slight sneezing and nasal discharge to severe hay fever symptoms and, in the six cases, asthma. Most of the patients responded quickly to 5 grains of potassium chloride given three times a day, some experiencing relief within a few minutes and some in about a half hour. Others, whose hay fever was mostly nocturnal, reported the next day that they had had much better nights. In only one case did an increase of symptoms follow an initial improvement, and this patient obtained adequate relief after the dose was increased to 25 grains (1.6 Gm.) of potassium chloride a day.

In one family of four, all of whom had severe hay fever, the two who were given the medicine responded; the other two continued to have hay fever. In another family of three sisters, all with severe hay fever, the one who was given the medication obtained complete relief; the other two continued to have severe hay fever. In the series of hay fever cases control studies by substituting inert medication were not carried out. One patient had a return of symptoms within twelve hours after he stopped taking his medicine and was again relieved as soon as it was resumed. In one case the medication was experimentally stopped and symptoms returned the following day; medication was resumed after three days and the symptoms disappeared satisfactorily. In a few instances, patients neglected to take their potassium chloride regularly and found that the omission of one dose resulted in a recurrence of symptoms, usually in from five to eight hours.

As is indicated in the table, every one of the patients experienced a degree of relief which in all cases was estimated as over 50 per cent and in most of them approximated 100 per cent. The first improvement noticed was the disappearance of irritation of the eyes. Within twenty-four hours the copious nasal discharge had almost entirely cleared. For about another day a few of the patients persisted in having a rare attack of dry sneezing. By the third day the patients who in the table are graded as having a 4 plus relief were free from symptoms. With the disappearance of sneezing and discharge, which in many cases interfered with sleep, the general state of health of these patients was greatly improved.

The following report illustrates the striking effect of potassium chloride in a severe case:

J. T., a boy aged 12 years, had had hay fever and asthma for the past eight summers, during the last four of which considerable relief had been obtained by desensitization with an allergen mixture. Injections had been omitted the past summer because of the illness of the patient's physician. The summer was spent on the Pacific coast, where the boy was practically free from symptoms. On returning to Tucson, however, during the ragweed and careless weed seasons, hay fever and then asthma started, and as these increased in severity diarrhea, abdominal cramping and then vomiting set in. In ten days the boy lost 15 pounds (6.8 Kg.). The patient could have been treated with epinephrine and ephedrine, or he could have been moved into a pollen-free atmosphere. It was decided, however, to try potassium chloride. The first dose was immediately regurgitated; half an hour later another dose was given and from that time on there was no sneezing, wheezing or vomiting. By the next day the cramping and diarrhea had disappeared. The medication was continued in 5 grain doses three times a day. At the end of a week he had regained about 10 pounds (4.5 Kg.) and felt fine.

The only complicating factor in this series was in case 28. This patient had not only hay fever and asthma but also urticaria, rheumatic heart disease and a long-standing, persistent, mild arthritis. This patient became entirely free from hay fever and asthma for two days but then had recurrent asthma and urticaria thought to be due to food sensitivity. This case will be reported in detail later.

Chemical studies of blood and urine, which had been done on the chronic asthmatic patients and which will be reported later, were not made in this group of hay fever patients.

*Chronic Asthma.*—The original studies on this phase of allergy were made on a group of ten patients with chronic persistent asthma. It is important to note that in none of them did any improvement occur from potassium chloride. Studies on these patients are being continued and will not be reported here in detail. It is sufficient to say that I have found in these cases that a "salt-free" diet seemingly decreases the severity of the asthma and that, furthermore, the administration of potassium iodide during the period of the "salt-free" diet practically eliminates severe asthmatic attacks. The beneficial effect thus obtained seems to be greater than would be obtained by the use of a "salt-free" diet or of potassium iodide alone. It should be made clear that these patients are, in general, not cured, although some of them are much better than they were before treatment was started.

*Other Allergic Diseases.*—In view of the excellent results obtained with hay fever it was thought advisable to record the results obtained in a small number of cases of other allergic diseases. Three cases of urticaria, two chronic and one acute, responded favorably to 5 grain doses of potassium chloride given three times a day. The skin in one case of long-standing thickly encrusted eczema was almost cleared in five days, leaving at that time only a brown-red discoloration to the smooth skin. In another case a mild eczematoid, itching lesion of the forearms disappeared in three days. Three patients with chronic sinusitis, apparently allergic, reported decrease of discharge and pain. In one of these acute severe frontal and antral pain completely disappeared in three minutes. In one patient with nasal polyps which had completely blocked the passage of air on both sides for three weeks, opening of the air passages occurred within an hour after a 5 grain dose of potassium chloride. The patient had expected to have nasal polyps removed, as had been done in the past, but has had practically no nasal blocking since this one simple experiment was tried three months ago. A Negro woman with nasal polyps completely blocking both nares was kept on potassium chloride 5 grains three times a day for two weeks, at the end of which time the polyps on the left side were seen to have partially shrunk, so that the anterior third of the left naris was free. One week later the left naris was sufficiently open to permit the passage of air. The results in these two cases encourage the belief that even severe nasal polyposis does not inevitably require surgery. In another instance, in which nasal polyps had recently been removed, potassium chloride was given and after two days the patient noticed marked freeing of the air passages. Dr. John Mikell, nose and throat specialist, who was unaware of the nature of the medication or of its mode of action, found at this time that the edema of the inferior turbinate had completely disappeared. In three typical cases of migraine relief

was obtained in only one, and this occurred within four hours after 20 grains (1.3 Gm.) of the potassium salt mixture was given. In two other cases no effect was produced with 15 grain and 30 grain (1 and 2 Gm.) doses of potassium chloride respectively.

It must be emphasized that these results are in no way to be considered conclusive. They are reported here only because, in some instances, various allergic disturbances seem to respond to potassium salt therapy.

*Food Sensitivity.*—A simple clinical experiment was tried on a man aged 44, who had for years regularly had acute nasal blocking (from polyps) and severe hives following the ingestion of shrimp, beer, candy in large amounts, or a combination of tomatoes and sugar, for each of which substances he had a penchant. He was asked to eat a portion of shrimp after taking 5 grains of potassium chloride. In his enthusiasm for the experimental method he took not only a large portion of shrimp but also a glass of beer, some tomatoes and sugar and then a large quantity of candy. No hives appeared but some rhinitis did develop, which was quickly relieved by the second dose of the medicine. The following morning he ate three tablespoonfuls of jam, which had also always given him hives and nasal blocking but which this time produced no symptoms at all.

#### COMMENT

From the results obtained in this study, as well as those reported by Rusk and Kenamore, it seems that potassium plays an important role in the mechanism of allergy. Obviously other electrolytes, including sodium, calcium, chloride and iodide, take part in this complex disturbance. Much recent work has shown the importance of altered electrolyte metabolism in endocrine disturbances, and it may well be that allergy is basically an endocrine dysfunction with secondary disturbances of electrolyte metabolism. This hypothesis, however, remains to be demonstrated. In view of the good results obtained in a few cases of asthma and eczema, with adrenal cortex extract, and in view of the known relationship in Addison's disease of the adrenal cortex to sodium and potassium disturbance, it seems probable that it is the adrenal gland that is primarily involved. Because of the well established relationship of epinephrine to allergic manifestations it would seem that this disturbance of the adrenal gland involves the medulla as well as the cortex.

This concept of allergy, indicating that the major disturbance is one of altered electrolyte metabolism, immediately suggests that the proteins produce manifestations only when the underlying electrolyte mechanism is disturbed.

It has been shown in this study that a much neglected simple inorganic chemical compound is of considerable importance not only in therapy but also in the study of a complex group of disturbances. It is hoped that this work will stimulate others whose facilities are more adequate.

#### CONCLUSIONS

1. Striking benefit was obtained from the use of potassium salts in twenty-nine cases of hay fever. These salts are also used in urticaria, eczema, nasal polyposis, chronic allergic sinusitis and migraine.

2. In chronic asthma potassium chloride is apparently ineffective; the use of potassium iodide, however, in combination with a salt-poor diet, seems helpful but not curative.

3. The method of administration of potassium salts is simple; no complication or "side effects" were noted, although further studies of toxicity are needed.

4. It is suggested that allergy is predominantly a disturbance of electrolyte metabolism associated with some endocrine (possibly adrenal) dysfunction.

## TOXIC HEPATITIS DUE TO SULFANILAMIDE

CURTIS F. GARVIN, M.D.

CLEVELAND

Although numerous toxic effects of sulfanilamide have been described, there are only a few references in the literature to damage to the liver produced by this drug. Hageman and Blake<sup>1</sup> have observed one case of toxic hepatitis presumably due to sulfanilamide. This patient recovered promptly when the drug was discontinued. Saphirstein<sup>2</sup> has recorded a severe but nonfatal case of toxic hepatitis caused by sulfanilamide. In this instance there was an associated exfoliative dermatitis.

Two deaths from hepatitis following the use of sulfanilamide have been reported by Bannick, Brown and Foster.<sup>3</sup> They felt that possibly their patients suffered hepatic damage prior to the beginning of the treatment and concluded that sulfanilamide may cause preexisting hepatic damage to progress to a stage from which regeneration is impossible. In contrast to this complication they have seen mild attacks of jaundice, which usually subsided rapidly when use of the drug was discontinued and intake of fluids was forced.

Long<sup>4</sup> in his experience with sulfanilamide has encountered jaundice with marked decrease of hepatic function on only one occasion. He believes that previous hepatic damage or jaundice is not necessarily a contraindication of sulfanilamide therapy.

This communication reports five cases of toxic hepatitis apparently caused by sulfanilamide, and increases the evidence that this drug is capable of causing severe damage to the liver.

CASE 1.—N. M., a white man, aged 25, who entered the Cleveland City Hospital Nov. 6, 1937, complained of a cutaneous disorder.

October 16 he had been started on a course of sulfanilamide as treatment for gonorrheal prostatitis. No other medication was administered. October 29 the patient had a chill followed by a fever of 38.5 C. (101.3 F.). The sulfanilamide was discontinued at once, a total of 50 Gm. having been given. November 4 a generalized cutaneous eruption appeared, and the patient became acutely ill. He entered the hospital two days later.

Examination showed the cutaneous eruption to consist of confluent red maculopapules with a few minute vesicles and pustules. General examination was otherwise negative except that the temperature was 38 C. (100.4 F.) and the liver and spleen were just palpable. Within the next few days the cutaneous eruption became more severe and icterus appeared. The edge of the liver was now 5 cm. below the costal margin.

3. Bannick, E. G.; Brown, A. E., and Foster, F. P.: Therapeutic Effectiveness and Toxicity of Sulfanilamide and Several Related Compounds. J. A. M. A. **111**: 770-777 (Aug. 27) 1938.

4. Long, P. H.: The Clinical Use of Sulphanilamide and Its Derivatives with Special Reference to Their Possible Toxic Effects, *Ohio State M. J.* **34**: 977-981 (Sept.) 1938.

On the third hospital day, the urine contained both bile and urobilinogen, and the icteric index was 63. On the sixth hospital day examination of the blood revealed sulfanilamide 0.2 mg. per hundred cubic centimeters, urea nitrogen 13 mg., sugar 83 mg., cholesterol 232 mg. and phosphatase 15.6 mg. The leukocytes numbered 19,000 per cubic millimeter and the erythrocytes 4,200,000. The hemoglobin was 12.1 Gm. per hundred cubic centimeters and a smear of the blood was normal. The Kline test for syphilis was negative.

During the next week the patient became deeply jaundiced, stuporous and very ill. The temperature varied between 38 and 40 C. (100.4 and 104 F.), the respiratory rate between 30 and 40 per minute and the pulse rate between 100 and 130 beats per minute. The cutaneous eruption progressed into a typical exfoliative dermatitis. The edge of the liver was now 10 cm. below the costal margin and the abdomen was distended with fluid. The urine contained large amounts of bile and urobilinogen, and the stools were light in color.

The therapy during this period consisted of a high carbohydrate-low fat diet, insulin, intravenous dextrose, blood transfusion, forced fluids, emollients and symptomatic treatment. On the thirteenth hospital day the patient began to improve. The temperature returned to normal. The fluid in the abdomen absorbed rather rapidly. The icterus slowly decreased, as did the bile and urobilinogen in the urine. The skin and the liver gradually returned to normal, and the patient was discharged on the thirty-eighth hospital day.

CASE 2.—G. B., a Negro woman aged 24, who entered the Cleveland City Hospital April 5, 1938, had received 33 Gm. of sulfanilamide from February 28 to March 10 inclusive for an infection of the pelvis. The patient then changed physicians and on March 16 received a single 0.6 Gm. dose of sulfanilamide, which caused her to have fever. Again on March 26 she received another 0.6 Gm. dose of sulfanilamide. No other medication was given. Following the last dose of sulfanilamide the patient's temperature varied between 38.5 and 39 C. (101.3 and 102.2 F.). March 30 she became icteric and the urine contained bile. The following day a generalized dermatitis appeared and thereafter the patient became acutely ill, entering the hospital five days later.

Examination showed a generalized exfoliative dermatitis and moderate jaundice. The edge of the liver was palpable 10 cm. below the costal margin. There was moderate thickening of both fallopian tubes. The urine contained bile grade 4 plus and urobilinogen grade 2 plus. The icteric index was 69. The erythrocytes numbered 2,500,000 per cubic millimeter, the leukocytes 30,000 and the value of the hemoglobin was 50 per cent. A differential count showed the leukocytes to be 50 per cent lymphocytes. The Kline test for syphilis was negative.

Therapy consisted of forcing fluids, high carbohydrate-low fat diet, intramuscular liver, ferrous carbonate by mouth, insulin, intravenous dextrose, blood transfusion and symptomatic treatment, but the patient became progressively worse and died April 10, on the fifth hospital day. Permission for a postmortem examination was not obtained.

CASE 3.—G. D., a white man aged 41, entered the Cleveland City Hospital Dec. 14, 1937, because of erysipelas of two days' duration. The patient said that he had drunk about 1 quart (liter) of whisky daily for the past fifteen years, although he had not taken any for a few days prior to his admission to the hospital.

Except for the erysipelas, the general physical examination was negative and sulfanilamide therapy was begun. No whisky or other medication was administered. On the third hospital day it was noted that the edge of the liver was 2 cm. below the costal margin. The sulfanilamide accordingly was discontinued at once, the patient having received a total of 26 Gm. The blood sulfanilamide was 15 mg. per hundred cubic centimeters. On the sixth hospital day the edge of the liver extended 6 cm. below the costal margin. The patient was jaundiced and the urine contained bile grade 4 plus. The stools were not acholic and the spleen could not be palpated. At this point the patient started to improve. The erysipelas and jaundice cleared rapidly and the liver decreased in size, the patient being discharged on the fifteenth hospital day.

Repeated blood studies showed no abnormalities except for leukocytosis at the time the erysipelas was present. The Kline test for syphilis was negative.

CASE 4.—T. J., a white man aged 40, who entered the Cleveland City Hospital Oct. 4, 1937, had received 35 Gm. of sulfanilamide from September 17 to October 3 inclusive because of chronic prostatitis. No other medication was administered. Two days before the sulfanilamide was discontinued the patient noted jaundice and vague epigastric pain.

General physical examination was negative except that the skin was moderately icteric and the liver extended 3 cm. below the costal margin. The urine contained large amounts of bile. Examination of the blood revealed the icteric index 63, phosphatase 18.1, phosphorus 2.6 mg. per hundred cubic centimeters, cholesterol 142 mg., sugar 83 mg., urea nitrogen 13 mg. The Kline test for syphilis was negative.

The jaundice gradually increased until the ninth hospital day, when the icteric index was 160. At this time the edge of the liver was 8 cm. below the costal margin. Thereafter the icterus slowly decreased and the liver returned to normal size, the patient being discharged November 9 in good health on the thirty-sixth hospital day. He was not seriously ill at any time nor did any anemia appear. Cholecystograms taken November 19 (ten days after discharge) were negative.

CASE 5.—T. M., a Negro aged 28, entered the Cleveland City Hospital Aug. 4, 1937, because of second degree burns of the left hand and left leg. In order to combat secondary infection, 44 Gm. of sulfanilamide was given from August 12 to August 22 inclusive without effect. The drug was again given from October 14 to October 17 inclusive, 16 Gm. being administered. The other medications given during this period were tannic acid, silver nitrate, boric acid ointment, potassium permanganate and dilute solution of sodium hypochlorite locally, and morphine, codeine, phenobarbital, acetophenetidin, acetylsalicylic acid and chloral derivatives. The Kline test for syphilis was negative.

November 30 a generalized erythematous maculopapular eruption appeared. Within the next week this progressed into an exfoliative dermatitis. The patient also became icteric and the edge of the liver, previously not palpable, was now 6 cm. below the costal margin. The icteric index rose rapidly to 115 and large amounts of bile appeared in the urine. There was no concomitant anemia. December 22 the skin started to improve and returned to normal rather rapidly. The icterus decreased slowly, as did the size of the liver. Feb. 4, 1938, when he was discharged, the icteric index was 20, the liver was no longer palpable and the patient felt normal.

#### COMMENT

In case 1 there is no reasonable doubt that sulfanilamide caused the dermatitis and hepatitis. No other medication was administered, and the cutaneous eruption was a typical dermatitis medicamentosa, the hepatic disease a typical toxic hepatitis.

The case is extraordinary in that there was simultaneous occurrence of jaundice and ascites with recovery. The first description of a case of jaundice and ascites with recovery is accredited to Jones and Minot<sup>5</sup> in 1923. Subsequently similar observations have been made by Bauer,<sup>6</sup> Weir,<sup>7</sup> Meyer and Learner,<sup>8</sup> McCabe and Hart,<sup>9</sup> Cavanagh,<sup>10</sup> Pavel and Runcan,<sup>11</sup> Forbes<sup>12</sup>

and Boros.<sup>13</sup> These reports have indicated that arsenamine, mercurial products, phosphorus, sodium gold thiosulfate, cinchophen, common duct stone, pressure of glands on the common duct and infections are agents which can so damage the parenchyma of the liver as to produce both jaundice and ascites and yet permit recovery. Evidently sulfanilamide can be added to this list.

In case 2 there seems to be little doubt that the dermatitis and hepatitis were caused by sulfanilamide. No other medication had been administered and the dermatitis and hepatitis in general resembled those in case 1. Either the patient had a chronic secondary anemia or the drug was hemolytic to erythrocytes. However, the size of the liver and the degree of icterus would indicate that an acute inflammatory process was present in any event and that the jaundice was not a manifestation of hemolytic anemia. Death in this case cannot be ascribed to the hepatitis alone in view of the fact that exfoliative dermatitis and anemia were also present.

Case 3 illustrates a less severe degree of hepatitis, occurring in this instance in a patient addicted to alcohol. No medication other than sulfanilamide was administered. Whether previous ingestion of alcohol renders the liver more vulnerable to sulfanilamide cannot be stated, although numerous other patients who have used alcohol to excess have tolerated the drug satisfactorily.

Case 4 reports a typical case of toxic hepatitis of moderate severity. No etiologic agent other than sulfanilamide can be incriminated. In this case, as in case 3, there were no other toxic manifestations.

The hepatitis in case 5 cannot be ascribed to sulfanilamide with as much certainty as in the other cases. In this instance there had been an interval of forty-three days between the last dose of sulfanilamide and the onset of symptoms. However, during this period no drug ordinarily considered as capable of causing toxic hepatitis and dermatitis had been administered. Furthermore, in the case of other hepatic irritants the length of time intervening between the actual administration of the drug and the onset of symptoms has been found to be quite variable, occasionally being as much as several months.<sup>14</sup> Whether this will hold true for sulfanilamide as it has in the case of other drugs remains to be seen. Certain it is that the hepatitis and dermatitis in this case were virtually indistinguishable from those in case 1 and case 2.

SUMMARY

Four cases of toxic hepatitis occurred during the course of sulfanilamide therapy. No other medication had been given to these patients. A fifth case developed after the use of sulfanilamide had been discontinued. In this instance the patient had received other medications but none ordinarily considered as capable of causing toxic hepatitis.

Three of these cases of toxic hepatitis showed an associated exfoliative dermatitis and one ended fatally. One case was extraordinary in that there was a simultaneous occurrence of jaundice and ascites with recovery.

This experience indicates that sulfanilamide should be added to the list of agents which may cause severe damage to the liver.

During the past eight months radioactive iron has been used in these laboratories as a tool in the studies of iron metabolism in dogs. This radioactive iron is prepared from the  $\text{Fe}^{58}$  isotope by deuteron bombardment

Its beta ray activity with a half life of forty-seven days makes this isotope useful as a labeled iron that may be followed in metabolism experiments even after mixture with the ordinary iron in the body.

Physiologists will admit that our understanding of iron metabolism is in a parlous state. There are diametrically opposed views relating to almost every phase of iron metabolism in the body. It is fair to state that much of this difficulty relates to methods of iron analysis. Many methods for iron analysis in body tis-

sues, fluids or feces carry errors so large as to render the results useless. These errors are due in part to various compounds of calcium and phosphorus.

If one may state (with allowance for varied opinions) the generally accepted story of the absorption and excretion of iron, it would read as follows: Iron is absorbed from the upper part of the intestinal tract in amounts depending on its concentration in the food, its form (ferrous or ferric) and gastric acidity; the surplus related to iron absorption, utilization and wastage is excreted in the lower bowel.

It came as a great surprise to us that iron is absorbed only in traces by a nonanemic dog but in abundance by the anemic dog depleted of its iron. This point is clear from a review of the accompanying table, but we are not prepared to say on what factors this difference rests—whether changes in mucosa, plasma or concentration of organic iron are of primary importance.

Five dogs were maintained on a diet low in iron and kept anemic by frequent bleeding. This has been shown to affect the depletion of iron stores. They were then fed iron containing the radioactive isotope on one or several occasions and the absorption of iron was followed by analysis of the circulating blood fractions. In three experiments the dogs were killed with ether after careful viviparfusion to remove all the circulating blood

From the Departments of Pathology and Radiology, the University of Rochester School of Medicine and Dentistry, and the Radiation Laboratory, University of California.

from the viscera. The value and limitations of this technical procedure have been discussed.<sup>1</sup> The content of radioactive iron in the liver, spleen and marrow was then determined, as shown in the table.

In another series of experiments, radioactive iron was fed to three normal dogs with iron stores well filled as the result of previous feeding of soluble iron salts and intravenous injections of neutral colloidal iron.

It is immediately apparent, even in this short series, that the nonanemic animal absorbs but little of the iron fed. Some of the anemic animals were not perfused in order that studies of excretion over long periods of time might be made, so we have no values for the iron content of the viscera. However, the rapid appearance of the isotope in the plasma and red blood cells alone is in marked contrast to the evidence in all the viscera and blood of the normal animals examined. The rapid appearance of radioactive iron in the red blood cells is of great interest. A discussion of the significance of these observations must await further experiments to indicate the relationship of this iron to the hemoglobin of the various types of red blood cells (nucleated, immatur and mature).

#### CONCLUSION

The evidence appears convincing that, in dogs under the conditions of these experiments, absorption of iron is dependent on the need of the body for iron.

### A REACTION TO THE ORAL ADMINISTRATION OF NICOTINIC ACID

W. H. SEBRELL, M.D.

AND

R. E. BUTLER, M.D.

Surgeon and Passed Assistant Surgeon, Respectively, United States  
Public Health Service

WASHINGTON, D. C.

Almost all the reports on the treatment of pellagra with nicotinic acid refer to unpleasant, but harmless, reactions. Fouts, Helmer, Lepkovsky and Jukes<sup>1</sup> treated three cases of pellagra with 500 mg. and one case with 1 Gm. of nicotinic acid. A sensation of heat and tingling on the skin was noted in all four cases. These sensations appeared within ten minutes, lasted from ten to twenty minutes, and were accompanied by dilatation of the peripheral blood vessels and slight, temporary fall in blood pressure.

The Smiths and Ruffin<sup>2</sup> observed a marked flushing of the face, neck, chest and arms a few minutes after intramuscular injection of 60 mg. of nicotinic acid, which lasted for fifteen minutes. A similar reaction followed the intravenous administration of approximately 12 mg. They note that the pulse, respiration and blood pressure were not affected and that there was no discomfort except for a slight feeling of warmth.

Spies, Cooper and Blankenhorn<sup>3</sup> noted severe flushing, itching and tingling, particularly of the face and

extremities, within twenty minutes after the administration of nicotinic acid in nine of thirteen persons. At the peak of the flushing there was no effect on blood pressure, temperature or respiration, and they state that in no instance did the administration of less than 50 mg. produce any effect, the reaction usually occurring only when large amounts were given.

France, Bates, Barker and Matthews<sup>4</sup> report mild generalized sensations of tingling and flushing in a case of pellagra a few minutes after the intramuscular injection of 60 mg. of nicotinic acid.

Spies, Bean and Stone<sup>5</sup> found that oral doses of 200 mg. of nicotinic acid or intravenous doses of 10 mg. nearly always produce a reaction within one minute. They noted reactions in about 5 per cent of 100 adults with an oral dose of 50 mg. and in about 50 per cent when 100 mg. was given. The reaction was characterized by flushing, burning and itching sensations with increased temperature of the skin and increased gastrointestinal motility. The pulse, blood pressure, respiration and electrocardiograms were not regularly changed.

Ruffin<sup>6</sup> states that 1 Gm. daily given in four doses invariably produces unpleasant sensations and flushing of the face and neck. In two of ten cases nausea and vomiting occurred.

Bogart<sup>7</sup> gave one patient 500 mg. daily until 8 Gm. was given and 300 mg. daily until 6 Gm. was given, and noted redness and warmth of the skin on only two occasions.

Rachmilewitz and Glueck<sup>8</sup> report one case of pellagra with tingling of finger tips, flushing of face and dizziness following 250 mg. of nicotinic acid for one day and 350 mg. daily for four days. In a second case severe itching occurred over the dermatitis, with flushing of the face, faintness and urticarial rash over the knees, back and arms following a second dose of 50 mg.

In view of these reports it seemed desirable to determine the quantity of nicotinic acid which may be given by mouth to healthy subjects without producing these unpleasant reactions which tend to make continued treatment with the drug more difficult. Accordingly, a group of eighteen healthy adult women were given an identical diet containing approximately 2,400 calories and low in the pellagra-preventive vitamin. Six were given 50 mg., six 30 mg. and six 10 mg. of nicotinic acid daily in aqueous solution added to 4 ounces (120 cc.) of tomato juice and taken with the mid-day meal. On the twelfth day of administration one of the subjects receiving 50 mg. daily (total intake of nicotinic acid 600 mg.) showed an intense flushing of the face, chest and back, accompanied by mild itching and a sensation of heat in the skin, which appeared in from ten to fifteen minutes after administration of the nicotinic acid and disappeared after about an hour. Following this first reaction, each daily dose of 50 mg. produced a similar reaction for eleven days. The dose was then divided into 25 mg. morning and evening. The flushing became much less marked and the subjective symptoms were milder but still occurred.

8. Rachmilewitz, M., and Glueck, Helen J.: Treatment of Pellagra with Nicotinic Acid, *Brit. M. J.* **2**: 346 (Aug. 13) 1938.

On the sixteenth day of administration a second subject receiving 50 mg. daily (total intake of nicotinic acid 800 mg.) showed a similar reaction of severe flushing of the face.

On the twenty-seventh day two more of the group receiving 50 mg. of nicotinic acid daily (total intake of nicotinic acid 1,350 mg.) showed similar reactions of slight flushing, itching and a sensation of heat. The remaining two subjects of this group did not show any reaction during a period of ninety-two days on the 50 mg. of nicotinic acid daily.

One of the six subjects receiving 30 mg. of nicotinic acid daily had a reaction on the thirty-second day (total nicotinic acid 660 mg.), characterized by an intense flushing of the face and neck, with itching and a sensation of heat. When the dose was continued the reaction occurred occasionally.

On the ninety-second day a second subject receiving 30 mg. daily (total intake of nicotinic acid 2.76 Gm.) had a similar reaction, which was unusual in that the flushing was restricted to the skin of the forehead, bridge of the nose, cheeks, back of the neck, shoulder joints, elbows, buttocks and knees. The remaining four subjects in the group did not show any reaction during the period of ninety-two days on the 30 mg. of nicotinic acid daily. None of the six subjects receiving the 10 mg. dose of nicotinic acid had a reaction at any time during the ninety-two days of observation.

The four subjects in the 50 mg. group who had reactions weighed 128, 101, 140 and 108 pounds (58, 46, 63.5 and 49 Kg.). The two who had no reactions weighed 165 and 111 pounds (75 and 50 Kg.). The two subjects in the 30 mg. group who had reactions weighed 119 and 113 pounds (54 and 51 Kg.). The remaining four weighed 147, 132, 99 and 143 pounds (67, 60, 45 and 65 Kg.). Thus there appears to be a considerable individual variation in reactions to nicotinic acid given by mouth which does not depend on the relationship between dosage and body weight, although this cannot be stated with certainty since the degree of saturation of the subjects with nicotinic acid at the beginning of the test is unknown.

In view of the fact that the reactions did not recur regularly in any of the patients except one in the 50 mg. group, and since Spies, Bean and Stone<sup>5</sup> report reactions within one minute from the intravenous injection of 10 mg., and the Smiths and Ruffin<sup>2</sup> report reactions from 12 mg. intravenously, it is not unlikely that one of the controlling factors in this reaction to the oral administration of nicotinic acid is the rate of absorption from the gastrointestinal tract.

#### CONCLUSIONS

Nicotinic acid in daily doses of 50 mg., given orally, produced transient, unpleasant but harmless reactions in four of six adult women on a diet restricted in the pellagra-preventive factor. A daily dose of 30 mg. of nicotinic acid produced a similar reaction in two of six women. Therefore reactions are to be expected in some persons on continued treatment with nicotinic acid in daily doses as low as 30 mg. by mouth.

Although the reactions are disagreeable, they persist only a short while and there is no evidence that any harm is done by them. Therefore their occurrence should not be allowed to interfere with the therapeutic use of large doses of nicotinic acid.

## THE PRIVATE PHYSICIAN'S ROLE IN THE NEW YORK CITY SYPHILIS CONTROL ACTIVITIES

CHARLES WALTER CLARKE, M.D.

Supervising Consultant

AND

THEODORE ROSENTHAL, M.D.

Director, Bureau of Social Hygiene, New York City  
Department of Health

NEW YORK

Not merely in words but also in action the New York City Department of Health has expressed its belief that the role of the private physician in the control of syphilis and gonorrhea is of paramount importance. There are about 15,000 private physicians in this city. They are in every neighborhood, available to aid diseased persons with advice, diagnosis and treatment. A large percentage of them welcome the opportunity to give medical care to persons having syphilis or gonorrhea and they welcome that official aid which enables them to render these services to a larger and larger number of victims of infection. They are willing to learn modern methods of diagnosis and treatment if they are not already familiar with them. They are willing to use modern diagnostic facilities, to seek consultation, to accept appropriate drugs, to report their cases, to cooperate in finding sources of infection, to notify the department of health regarding lapsed cases and to aid in popular education of the general public regarding syphilis and gonorrhea. They benefit and the official health agency benefits by this cooperation.

The health department should study seriously and frequently the question What can we do to help private physicians find, treat and keep under treatment more and more persons with gonorrhea and syphilis, especially those who can pay a fee, even though a very modest one? No health department can afford to neglect measures for obtaining the cooperation of private physicians. If the cooperation of the official agency is sincere—with emphasis on the "co"—and not merely a onesided demand for reports and red tape performances from private physicians, the results will be satisfactory to all concerned.

Cooperation with private physicians was the basis of the policy of the New York City Department of Health when in October 1935 Commissioner John L. Rice created a Bureau of Social Hygiene to develop a program for the control of syphilis and gonorrhea in our population of seven and a half million people. Administrative details have been carefully considered with the medical advisory committees of the department and of the several health districts of the city.

As a preliminary step in this process of cooperation with private physicians a twofold plan of disseminating popular and professional information was set up. In order to meet the needs of practitioners who were not thoroughly familiar with modern methods of diagnosis and treatment of syphilis and gonorrhea, four post-graduate clinical courses, each of six weeks' duration and requiring attendance three times weekly, were given in succession in 1937. Registration was limited to ten physicians for each of these sessions, which included lectures and clinical demonstration. During the spring of 1938 a "refresher course" was held once a week for six weeks; the attendance throughout was maintained at seventy doctors for each meeting. In fact, this course was so well received that it was

decided to hold a similar series during the summer months. In spite of the seasonal inactivity, an average of forty physicians attended each session. Local and national medical groups holding periodic meetings in New York City include in their programs sections on control of syphilis and gonorrhea. For example, during the week of the annual meeting of the American College of Physicians, one section met daily at the

Chart 1.—Specimens tested for private physicians, health department laboratory, 1935-1938.

department of health for lectures, discussion and clinical demonstration on problems of research in and diagnosis and treatment of these diseases. The Academy of Medicine sponsored a series of lectures on syphilis and gonorrhea in 1937. In addition to these educational activities, informative literature is distributed by the department of health for professional use. In 1936, 1,400 physicians in the city received a practical pamphlet on syphilis, and during the first half of 1938, 2,107 pamphlets entitled "Syphilis—Its Diagnosis and Treatment" were sent to local practitioners.

Private practitioners have in turn united with the health department in enlightening the general public. During the 1937-1938 season, forty-five doctors, not connected with the department in any way, gave eighty-one lectures, accompanied by film showings, to general

Chart 2.—Number of private physicians receiving drugs, October 1936 to June 1938.

lay audiences. These doctors are included in a panel of speakers and generously volunteer their own time, without remuneration, to cooperate in the popular educational program. Thousands of physicians participate by distributing large quantities of literature, consisting of simple explanations of facts about syphilis and gonorrhea prepared in various languages for different population groups.

All educational propaganda issue by the department of health stresses the desirability of undergoing examination and treatment, if necessary, by the family physician. Every possible aid is extended to the doctor in carrying out this objective. Among diagnostic services offered the physician is free laboratory service, including blood, dark field and spinal fluid examinations for syphilis and smear tests for gonorrhea. One-half million such tests are performed annually in the health department laboratories, and of these more than 50 per cent are sent in by private physicians. That this service is constantly increasing is evident by chart 1.

Private physicians may send their patients to any one of twenty centers for diagnostic and consultation services; the results of such examinations, which vary from the taking of a specimen to performing a complete examination for a venereal disease, are sent directly to the physician referring the patient. Table 1 indicates the number of laboratory specimens taken in health department clinics on patients referred by private physicians; it will be noted that an increase of 20 per cent over the number examined in 1937 is expected in this service during 1938.

The department of health has repeatedly announced that persons wishing to place themselves under the care of private physicians can obtain the names of private physicians from the diagnostic and treatment centers of

Chart 3.—Private physicians visited by epidemiologists, 1937-1938.

the department. The five county medical societies of New York City have supplied the department with names of doctors qualified and willing to receive patients referred by the department for diagnosis and treatment of syphilis and gonorrhea at moderate fees. Five of these names, selected in strict rotation, are given to each applicant for private medical care, who makes his own final selection of a doctor. Since this system was begun early in 1937, more than 600 persons have been so referred.

However, when a patient cannot afford even these substandard rates for diagnostic services, he is examined and later referred to a private physician for treatment if necessary and if his economic status permits. From 200 to 300 persons annually are referred to private physicians for treatment subsequent to examination in health department clinics. A reciprocal relationship allows the private doctor to send his patients to the health department for treatment if he finds such an arrangement desirable; more than 1,000 patients are referred by private physicians each year for treatment by the department of health.

One of the most important items in placing and keeping patients under the care of private physicians is the practice of the distribution of free drugs for the treatment of syphilis. From August 1936, when distribution began, through June 1938, a period of twenty-two months, 420,448 doses of drugs were given

to private practitioners for the treatment of their private patients, regardless of their economic status and in sufficient amounts to give thorough and complete treatment. More than 600 doctors a month receive drugs for the treatment of almost 1,000 patients. Chart 2 indicates the extent to which this practice is expanding.

The problems of helping physicians to find new patients with syphilis and gonorrhea and keep them under their care have been satisfactorily solved by the methods briefly outlined. However, the necessity for extending these services to provide for the investigation of contacts, sources of infection and the follow-up of delinquent cases was met by employing, in December 1936, a staff of four medical epidemiologists and eight nurse epidemiologists. Any physician is at liberty to request the assistance of a member of this group, who, for the duration of his relationship with the physician, serves under the latter's supervision.

Medical epidemiologists, on request, frequently confer with doctors regarding their problems of diagnosis and treatment and help them bring in for examination possible sources of infection and contact to their patients. Chart 3 indicates the number of visits made to private physicians by epidemiologists, at the physicians' request.

During 1937, 433 named possible sources of infection were referred by doctors for investigation, of whom

TABLE 2.—Reported Cases of Syphilis and Gonorrhea in New York City During First and Second Quarter of 1938

Reporting Agency	First Quarter	Second Quarter	Percentage Increase
State Department of Health	1,506	3,542	135
City Department of Health	4,149	5,489	32
Private Physicians	2,593	5,857	126
Other	35	1	-97
Totals	8,283	14,889	80

134, or 31 per cent, were subsequently proved sources of infection. They also referred 217 contacts to their patients, of whom 204, or 94 per cent, were brought in for examination. Thus, it is obvious that one of the major obligations of the medical epidemiologist is serving the private practitioner in any capacity relevant to the control of syphilis and gonorrhea.

Nurse epidemiologists follow up patients reported as delinquent by private physicians; in their dealings with these patients they act as agents of the doctors. Their chief concern is the return of the patient to the referring physician; if such action is impossible, the nurse makes an effort to place him under other medical supervision. During the second quarter of 1938 a brief study was made of the results of following up and tracing delinquent patients reported by private practitioners. In this period 360 new referrals were made, of which 270 were terminated. Of these 270 terminations, 103 were not found because the patient had given the physician a false address or because the patient had left the city. Thus 167 of these persons were located, of whom 50 per cent were returned to private physicians. Most doctors are not able to follow up their own delinquent patients and find it very convenient to enlist the help

of a nurse epidemiologist. As more doctors become familiar with this service, more of the nurses' time is devoted to their patients. Chart 4 shows the ratio of private physicians' cases to the total number of lapsed cases referred for follow up since the beginning of 1937, when this item in the control program was introduced.

Chart 4.—Cases referred by private physicians for follow up by nurse epidemiologists.

Case reporting by private physicians has improved to the extent at which it is now possible to omit positive laboratory reports from the official case count. Every physician who submits to the health department laboratories a positive blood or smear specimen is sent a letter requesting him to report the patient if a diagnosis of syphilis or gonorrhea is made and if the report had not previously been made. These individual letters

are not only directly responsible for the great improvement in case reporting but have also proved to be a valuable means for bringing to the attention of the department delinquency in treatment. This system was instituted during the first quarter of 1938 and has begun to produce excellent results. During the first three months of the year 8,281 cases of syphilis and gonor-

rhea were reported as compared with 14,889 for the second quarter, an increase of 80 per cent. It is particularly interesting to note that private physicians have improved their official case reporting during that time by 126 per cent and now constitute the largest reporting agency, as indicated in table 2.

The greatest problem still remaining in this program of coordinating the activities of the medical and public health professions is that of acquainting more doctors with the services offered them. In their efforts to inform their members of health department activities in this connection, the local medical societies have published progress reports and occasional editorials in their official bulletins. The department of health has repeatedly circularized the profession by means of general letters, through the press and by personal contact as well as through the laboratory, which sends announcements (such as the card reproduced herewith) in a routine manner with reports on specimens. The demand for services is rapidly increasing as a result of this publicity; the department will continue to keep pace with this growing interest by emphasizing cooperation with the medical profession.

#### SUMMARY AND CONCLUSION

In New York City the department of health offers to private physicians postgraduate educational opportunities, all diagnostic and consultation services, epidemiologic and follow-up services, and drugs for the control of syphilis and gonorrhea. The private practitioners of the city have welcomed these services and have given their cooperation in finding and treating these diseases.

50 West Fiftieth Street.

## Clinical Notes, Suggestions and New Instruments

### SENSITIZATION REACTION TO SULFANILAMIDE

E. B. ROGERS, M.D., EL PASO, TEXAS

Many reports of eruptions of the skin have been described as having resulted from sulfanilamide. Dermatitis medicamentosa, a simple maculopapular rash, has appeared during the second week of treatment in about 6 per cent of cases.<sup>1</sup> It usually disappears in two or three days after treatment has been discontinued. Erythematous eruptions covering part or all of the body have been described<sup>2</sup> and there have been some cases of exfoliative dermatitis which cleared up only after several months.<sup>3</sup> Only one report of definite sensitization to the drug has come to my attention, in an unpublished personal communication; hence the following case report seems worthy of notice.

#### REPORT OF CASE

Mrs. R., aged 58, an American housewife with two children, gave a past history of allergy. In 1921, to relieve severe pruritus vulvae, a resection of the left ilio-hypogastric and ilio-inguinal nerves was done under 1 per cent procaine hydrochloride local anesthesia. Later a tooth was extracted with procaine hydrochloride as the anesthetic agent. No reaction resulted. In 1923 a sebaceous cyst was removed from the back of the neck under procaine hydrochloride. After about a week an area of redness appeared in the surrounding skin which had the appear-

ance of an infection, but there was no pus at any time. There was much itching, which disappeared together with the redness in about three weeks. Three years later another dentist blocked a nerve with tutocain, assuring her that this was not procaine hydrochloride and would not produce a reaction. However, a severe reaction followed with redness and swelling. The gums healed slowly over a period of three or four weeks. At another time the addition of butyn to a prescription for pain in the left eye caused redness, itching and closure of the eye from swelling within twenty-four hours. The reaction was severe for a week and cleared up in three weeks. In 1930 a thoracentesis was done by one of my associates, who used procaine hydrochloride, not knowing the patient was allergic to this anesthetic. Resection of a rib was then done under gas. The area about the wound became red after a few days but the patient was too ill with empyema to note subjective symptoms.

In 1935 the patient had erysipelas originating in a small area of eczema above the right ear, which yielded to treatment with ultraviolet rays. Early in May 1938 a threatened return of the erysipelas led to sulfanilamide therapy. She took five tablets, a total of 25 grains (1.6 Gm.) in thirty-six hours. The next morning her left eye was red and the lids were greatly swollen. The conjunctiva was much congested and there was marked lacrimation. Bright red erythema covered the lids and spread over about 1 inch (2.5 cm.) of the surrounding skin. Itching of the lids was intense, especially along the margins and at the outer canthus. The right eye was normal. At the same time an area of erythema and swelling appeared in the left groin, centering over the site of the resection of the nerves, and extended gradually for a period of about two weeks. The swelling extended about 3 inches (7.6 cm.) in advance of the erythema and was marked by a sharply defined raised border similar to erysipelas, but the tissues were very soft. The temperature and pulse were normal throughout.

In the succeeding three to ten days every site of a previous application of a local anesthetic flared up in reaction—bright red erythema, itching, swelling and tenderness on pressure. The site of injection on the neck flared up on the third day, the site of injection for resection of the rib on the sixth day and the buccal mucosa about the tenth day, and later the eczematous area was found to present a red rash. The time of appearance and the intensity of reaction in all three areas seemed to depend on the quantity of anesthetic that the tissues had received at the time of operation. The eye, commonly used for sensitization tests, reacted first, and no one could fail to see that the ophthalmic reaction was strongly positive. The reaction on the groin spread over the abdomen and both thighs. The erythema in the neck and chest reached diameters of 6 and 10 inches (15 and 25 cm.). The reaction in the patch of eczema was small; it probably resulted from an external application of an anesthetic ointment. The reaction of the buccal mucosa was limited to the mucous membrane of the mouth, tongue and throat. The process in all the affected areas reached its height during the third week, at which time fully one third of the body surface was involved. Decline of the reactions then began very slowly, and at the end of five weeks there is still itching and erythema in the groin and on the back. She is not allergic to proteins, unless the eczema is of that nature.

An intolerable itching in all the affected areas was the principal symptom. Neither epinephrine nor ephedrine had any effect. The best relief was obtained from antipruritic lotions containing phenol or from the soothing effect of starch water. At one time the patient applied ethylaminobenzoate (anesthesin) ointment over a small area, which gave temporary relief but later aggravated the symptoms. Barbiturates were necessary for sleep.

The chemical formulas are given here for comparison:

Procaine hydrochloride—para-amidobenzoyl diethylaminoethanol hydrochloride.

Tutocain—para-aminobenzoyl dimethylaminomethyl-butanol hydrochloride.

Butyn—para-aminobenzoyl gamma-di normal butylaminopropanol sulfate.

Sulfanilamide—para-aminobenzene sulfonamide.

Anesthesin—ethyl aminobenzoate.

1. Schwentker, F. F., and Gelman, Sidney: Bull. Johns Hopkins Hosp. 61: 136 (Aug.) 1937.

2. Finney, J. O.: Severe Dermatitis Medicamentosa Following the Administration of Sulfanilamide, J. A. M. A. 109: 1982 (Dec. 11) 1937.

3. Myers, G. B.; Vonder Heide, E. C., and Balcerski, Matthew: Exfoliative Dermatitis Following Sulfanilamide, J. A. M. A. 109: 1983 (Dec. 11) 1937.

The base of each of these compounds is aminobenzene (aniline). From the injections of procaine hydrochloride the patient evidently became sensitized to compounds containing this base. If the sulfanilamide had been given by injection the result would doubtless have been the same—a flare-up reaction in areas that had previously been sensitized. Cutaneous scratch tests gave a positive wheal to 2 per cent procaine hydrochloride in twelve hours, redness in twenty-four hours, followed by itching and swelling in the subcutaneous tissues which increased gradually for a week before recession began. There was a slight reaction to aminobenzene, none to sulfanilamide. Patch tests gave negative results. Eight days after the patch tests were applied the 2 per cent procaine test gave a positive result with a papulovesicular (2 cm. in diameter) rash that faded out slowly, about two weeks later. The notable feature is that a drug taken by mouth should produce reactions at the sites of injections made years before and at no other place. This would seem to mark the process as a form of allergy but differs from food allergy in that the reaction occurs only in areas previously sensitized by some derivative of the aminobenzene base.

# STANDARDS FOR RED BLOOD CELL INCREASE AFTER LIVER AND STOMACH THERAPY IN PERNICIOUS ANEMIA

RAFAEL ISAACS, M.D.; FRANK H. BETHELL, M.D.; MATTHEW C. RIDDLE, M.D., AND ARNOLD FRIEDMAN, ANN ARBOR, MICH.

Data from 129 selected patients with pernicious anemia in relapse, adequately treated with liver extract intramuscularly, and twenty-one patients treated with desiccated, defatted stomach tissue have been analyzed to note the rate of increase in the red blood cell count. The dosage of liver extract averaged the

Chart 1.—The red blood cell count after one, two, three and four weeks of intramuscular liver extract therapy. Example: With an initial red blood cell count of 2 million per cubic millimeter the count at the end of one week will be 2.55 million, at two weeks 3 million, at three weeks 3.5 million, at four weeks 3.8 million.

equivalent of from 1 to 2 units daily, and the desiccated stomach dosage was usually 40 Gm. daily for the first two weeks.

In chart 1 the red blood cell count at the beginning of intramuscular liver extract therapy is plotted against the red blood cell count at the end of one, two, three and four weeks. A separate line is drawn for each week. The lines have been smoothed and corrections have been made for deviations due to manifest abnormalities and inadequate data at various points, as indicated by evident interpolations. Data from more than 500 cases were available for such changes.

In chart 2 the same data are plotted, showing the average rate of formation of red blood cells after intramuscular liver extract therapy, in terms of weekly changes for each initial count. From the trend of these lines, checked by available

From the Thomas Henry Simpson Memorial Institute for Medical Research, University of Michigan.

data, the positions for five, six, seven and eight weeks are indicated. If the rate remains unchanged a count of five million red blood cells per cubic millimeter may be expected at the end of eight weeks, regardless of the initial count. Many factors may modify this in individual cases, such as infection, deficiency of iron and an abnormal rate of blood destruction.

Chart 2.—The red blood cell count, at weekly intervals, for each initial red blood cell count after liver extract therapy, intramuscularly. Example: With an initial red blood cell count of 1 million per cubic millimeter the count at the end of one week will be 1.7 million, at two weeks 2.4 million, at fifteen days 2.5 million, and so on.

The rate of increase of red blood cells is slower during the first two weeks after desiccated defatted stomach tissue is given than after intramuscular liver extract (chart 3). An analysis of these data, if plotted with "weeks" as ordinates and the "initial red blood cell count" as abscissas, shows that the rise in the red blood cell count, after stomach medication, is very slight during the first week, contrasting with the more rapid increase after intramuscular liver extract medication. It is pos-

Chart 3.—The red blood cell count after one and two weeks of therapy with desiccated, defatted stomach tissue. (See example in legend for chart 1.)

sible that this is related to the speed of absorption of the material by the intramuscular route. The slope of the line shows that the rise would begin on the fourth day of treatment with stomach.

## SUMMARY

Standards are given for the red blood cell counts, at weekly intervals, for patients with pernicious anemia treated with liver extract intramuscularly and for desiccated defatted stomach therapy.

## QUININE IN MYOTONIA CONGENITA

ROBERT B. LONERGAN, M.D., AND HARRY A. PASKIND, M.D., CHICAGO

In 1936 Wolf<sup>1</sup> reported startling effects of quinine in states of myotonia. He treated three siblings with myotonia congenita and one patient with myotonia atrophica with quinine and found that all myotonic manifestations disappeared. He reported that 10 grains (0.65 Gm.) of quinine dihydrochloride injected intravenously abolished every myotonic phenomenon within ten minutes after administration, the effect lasting from fifteen to twenty hours. He further found that quinine hydrochloride from 5 to 10 grains (0.32 to 0.65 Gm.) given by mouth two or three times a day proved to be an adequate maintenance dose for the eradication of the myotonia.

Wolf tried the remedies previously used in such states, such as thyroid substance, atropine, posterior pituitary, calcium chloride, salicylic acid and calcium gluconate, and found them without effect on his patients. Various stimulants and depressants of the autonomic nervous system and several alkaloids he found equally ineffective.

Wolf concluded that quinine is a specific for myotonia.

Previously Lindsey and Curnen<sup>2</sup> presented evidence in favor of the view that the after-contraction of myotonia is of reflex origin and is due to the persistent discharge of hyperexcitable sensory end organs in muscle. It seemed reasonable to Wolf that quinine produced effects by diminishing this reflex action. Pharmacologically it had been known before that quinine produces a transient increase in strength in skeletal muscle, followed shortly by fatigue and weakness of contraction, that it produces vascular dilatation and is an antagonist to epinephrine, and that it depresses the vagus termination.

At the meeting of the American Neurologic Association in 1937 Wolf presented a paper in which he showed cinematographically the dramatic changes produced by quinine in one of his patients with myotonia.

In 1937 Kennedy and Wolf<sup>3</sup> reported the results of treatment with quinine in four additional patients with myotonia, three of whom had myotonia atrophica and one myotonia congenita. Again they found that quinine hydrochloride, given by mouth in doses of from 5 to 10 grains, was followed by disappearance of the myotonia. They also reported that quinine and prostigmine are antagonistic in action, quinine aggravating the symptoms of myasthenia gravis and prostigmine having the same effect in myotonia.

In discussing the pathogenesis of myotonia, Kennedy and Wolf pointed out that endocrine factors may play a part. Thus, myotonia had been observed periodically during the menses, its cessation had been observed after the birth of a child, and improvement had been noted after administration of calcium and parathyroid. As a result of experiments, Kennedy and Wolf concluded that the myotonus of myotonia congenita is a pathologic condition of the muscle or neuromuscular junction, independent of the central nervous system and, further, that quinine relieves myotonus primarily by direct action on the muscle or at the myoneural junction. They came to this conclusion after determining experimentally that spinal anesthesia does not abolish myotonia but that administration of quinine in a person previously given spinal anesthesia does abolish myotonia. They also postulated that the effectiveness of quinine in myotonia may be due to inhibition of acetylcholine production, but they felt that there were other factors at work of which there was little or no knowledge.

In another communication Kennedy and Wolf<sup>3a</sup> reported their experience with quinine in the treatment of myotonus extended over six cases of myotonia congenita and fifteen cases of myotonia atrophica for a period of one year. In not a single case did quinine fail to eradicate the myotonia. They found that any form of quinine, whether the hydrochloride sulfate,

bisulfate or hydrobromide, was effective in doses of from 2½ to 15 grains (0.15 to 1 Gm.) by mouth two or three times a day. In only one case did symptoms of cinchonism appear, as manifested by ringing in the ears.

The only other communication we have been able to find on this subject is one by Smith<sup>4</sup> in which he reported that in three cases of myotonia congenita the symptoms were entirely abolished by quinine.

## REPORT OF CASE

A youth aged 14 was first seen by us Sept. 6, 1937. The father had had two nervous breakdowns, characterized principally by depression, from both of which he recovered. The mother, the maternal grandfather and a maternal uncle all had a curious deformity of the little finger; the terminal phalanx did not lie in a straight line with the middle phalanx but instead made an obtuse angle with it. A sister, now 14 years of age, as far back as could be remembered had slight difficulty in starting to walk or run; the upper extremities were normal. We were not afforded the opportunity of studying the sister's case. The family history was otherwise negative.

The patient was the first born, born less than two years after marriage at full term. Labor was very difficult with face presentation, delivery by forceps and severe laceration. There was neither postnatal asphyxia nor convulsion. Infantile history was negative except that at first he gained weight poorly; only at the end of three months did he regain his birth weight. He had had only the ordinary diseases of childhood.

At 14 months he began to walk, and it was noted that for about one year he walked on his toes; this manner of walking then gradually disappeared. At 3 or 4 years the parents noticed that he had difficulty in starting movements, i. e. in starting to walk, in getting up from a sitting position, in climbing stairs and in starting to run. The parents were not aware of difficulty in the use of the hands, but in gross use of the arms, such as in throwing, they noticed the same difficulty in starting. All difficult movements would become easier with repetition, but hardly completely normal. Under conditions in which haste was required or under emotional strain, the disability was especially marked. This condition had been present since the onset. The disability was always worse in the morning or after a long rest but never completely gone at any part of the day, but it was alleviated considerably by exercise. There were no mental symptoms. The patient was a straight A student.

Examination disclosed the typical herculean musculature so often seen in this condition. This was especially pronounced in the quadriceps group, but the muscles of the calf, shoulder girdle, arms, back and neck also showed herculean conformation. Myotatic irritability was marked; striking with a hammer produced a furrow over any part of the skeletal muscles. The myotonic disability was easily demonstrated; there was difficulty in starting to walk, to run or to climb stairs and in squatting or getting up from a squatting or sitting position. The disability was present but less evident in the upper extremities and here was most marked in the hands and fingers; there was difficulty in grasping or shaking hands. In all affected parts the disability diminished but did not disappear after several attempts. The muscles innervated by the cranial nerves were spared; there was no difficulty with the muscles of expression, mastication, deglutition and none with the extra-ocular movements and tongue. Sensation was intact. All deep reflexes were diminished; plantar and abdominal reflexes were normal. Examination of the cranial nerves yielded negative results.

The patient had a high narrow palate, two colored irides, brown speckled with blue, and deformed fingers like those described in the mother and other members of the mother's family.

The basal metabolic rate was normal. Examination of the blood, the Kahn test on the blood and chemistry of the blood yielded negative results.

A diagnosis of myotonia congenita was made.

The patient was given quinine sulfate 5 grains three times a day. This produced improvement at once but not eradication, and increasing dosages had the same effect, i. e. amelioration only, until 10 grains was given five times a day, when disappearance of the myotonic phenomena occurred. With this

dosage, starting to walk, run, sit up, run upstairs, shake hands and the like presented no difficulty. He was kept on this dosage for one week. After this the dosage was gradually diminished until he took one dose of 15 grains at 7 a. m. This eradicated the hypertonia until 6 p. m., and if his evening's activities required easy movements he took another 10 grains at 6 p. m.

He was last seen in August 1938. At that time he continued free from myotonic symptoms during the day if he took 15 grains of quinine sulfate in the morning, and this freedom from myotonic symptoms was continued throughout the evening if he took 10 grains more after supper.

On only two occasions were symptoms of cinchonism present in the form of ringing in the ears for short periods, and then only when he was getting 50 grains (3.2 Gm.) of quinine sulfate a day.

#### CONCLUSION

In a case of myotonia congenita we have been able to confirm the value of quinine as reported by Wolf, Kennedy and Wolf, and Smith.

### CONFERENCES ON THERAPY

#### I. TREATMENT OF PAIN

*NOTE.—These are actual reports, slightly edited, of conferences by the members of the Departments of Pharmacology and of Medicine of Cornell University Medical College and the New York Hospital. The questions and discussions involve participation by members of the college staff, students and visitors. The next report will concern "The Treatment of Coronary Disease."—ED.*

DR. McKEEN CATTELL: These conferences were inaugurated as a joint undertaking of the Departments of Medicine and of Pharmacology with the idea of stimulating interest in rational therapeutics. Representatives from the clinical departments and from the laboratory departments lead the discussion. Free and informal discussion represents the most important part of these conferences.

DR. HARRY GOLD: The symptom pain stands high, if it does not actually lead, the list of causes of disability. It is probably the most frequent symptom requiring attention in the practice of medicine. If one were to survey a fair sample of the results generally obtained with drugs for the treatment of pain, one would discover that they are not as good as they might be. The outstanding deficiencies fall into two classes:

1. First, one finds a considerable proportion of failures to abolish the pain. The primary objective seems often not to be attained.

2. Second, in a fair proportion of cases, whether the pain is controlled or not, other effects, disagreeable and sometimes disastrous, result: nausea, vomiting, constipation, distention, urinary retention, temporary blindness, deafness, skin eruptions, profuse perspiration, stupor, methemoglobinemia, agranulocytosis, acute yellow atrophy of the liver, and narcotic addiction. This is but a partial list of one that could be very much more formidable, representing the untoward reactions that follow the use of agents employed for the relief of pain.

All of this indicates that there are no ideal pain-relieving substances; our task is to consider what we need to do in order to make the drugs or medicinal agents at our disposal as effective and as safe as possible in the control of pain.

Every case of pain presents a problem. The use of drugs to control pain involves a judgment which grows out of the careful appraisal of many facts. There is a prevailing tendency in a case with pain to dig down into our bag of analgesics, fetch up something that is supposed to kill pain, and prescribe. If we do that, the range of successful treatment becomes relatively small indeed, and alongside of the little good that we do, in that way, there stands enough harm to eclipse it. Illustrations of these remarks will appear in matters that will be discussed presently.

What are the matters one needs to consider as a basis for the use of drugs in the treatment of pain, in a manner likely to yield the greatest returns with the least risk?

1. Pain is a symptom and not a disease. In our zeal to relieve it, or in our success in relieving it, there is always the danger of overlooking the less obvious and less dramatic aspect of the case, the disease itself. Recently I encountered the case of a nurse who had suffered attacks of thoracic pain. With the approval of the house officer she took large doses of an analgesic agent and obtained relief. The last attack did not respond as effectively as the previous ones, whereupon a careful examination was made. The results showed that she had been carrying on her nursing work with a pleural effusion and active pulmonary tuberculosis. This is the sort of thing one occasionally encounters. We must bear this fact in mind constantly, that pain is a symptom and not a disease, if the relief of pain is not from time to time to prove to be a misfortune.

2. Pain labels a disease and its location. This is another fact of some importance and is closely related to the statement previously made. You have all probably heard about cases, or perhaps you know of some from your own experience, of peritonitis directly attributable to the overzealous relief of abdominal pain before a definite diagnosis has been made.

3. The cause of pain is important to determine. We all know that it is necessary to ascertain whether the cause of a headache is a brain tumor or some insignificant functional disturbance so that the cause (the tumor) may be removed. But I have in mind something less than that. From the standpoint of relief alone without removal of cause, a clear appreciation of the cause is often very helpful. For example, of three kinds of pain in the chest, the pain of intercostal neuralgia, the pain of effort angina and the pain of coronary thrombosis, differentiation is sometimes extraordinarily difficult. The agents which relieve one may be ineffective in the other. One can group other types of pain in that way; for example, pain in the legs due to myositis, vitamin B<sub>1</sub> deficiency or vascular disease. The effectiveness of the relief of the pain aside from the question of removing the cause depends here on a differential diagnosis.

4. The pathogenesis of pain is a matter of some importance; whether, for example, the pain is caused by spasm of smooth muscle or anoxemia or comes about as the result of inflammatory reactions around nerve fibers or endings.

5. The severity of the pain ought to be considered. Perhaps it is not sufficiently severe to require relief by therapeutic agents. Not infrequently when you are about to prescribe for a patient with pain the patient will ask you what the medicine is for, and you will say "For your pain." He may reply "I don't like medicines. I am not much interested in the relief of the pain so long as my mind is relieved that the cause is not

serious." Before we prescribe a drug, the question should be put whether the relief will recompense the patient for other forms of discomfort which the drug may cause. You will see patients taking two or three doses of codeine a day for the relief of very mild anginal pains. The price is disagreeable stupor and troublesome constipation. Such pains can often be much better controlled if we take the trouble to assist patients in making the necessary adjustments to reduce their activities to a level within their capacity without pain.

6. The natural course of the pain is also significant: Is it going to last a few hours or several days? Is it going to recur over long periods of time? Is it the kind of pain the intensity of which is likely to fall from its peak very gradually or is it likely to subside very abruptly? Morphine poisoning often arises from the use of large doses of the drug in patients in whom severe pain subsides abruptly. In such a case the morphine may seem to be producing very little depression, and the doses are repeated to secure more relief of the pain. With little warning, however, you find the patient lapsing into a state of profound stupor with depressed respiration, and you wonder what has happened. You have used large doses of morphine in a variety of pain which tends spontaneously to come to an end rather

#### *The More Common Analgesic Agents*

<i>A. Raise Thresholds</i>	
1. <i>Opium Group:</i>

Neocinchophen	3. Caffeine
	4. Vitamin B <sub>1</sub>

abruptly, leaving the patient under the influence of an amount of morphine which is toxic in the absence of pain, for pain is an antidote to morphine!

7. The psychic element in pain may vary anywhere from an insignificant role to the sole cause of the pain. That needs to be considered also from the standpoint of the kind of analgesic agents that are to be used. Fear and anxiety increase the perception of pain, and the use of small doses of sedatives greatly enhances the effectiveness of some of the analgesic agents. When reasonable procedures in a given case seem to be without influence on the pain, one might well ask whether the patient wants his pain relieved; the pain in this case may be one of the patient's most precious possessions. That needs to be considered before one goes on increasing the doses of drugs or shifting from one preparation to another in the endeavor to relieve it.

8. Finally, drugs are only adjuvants in the treatment of pain. Physical therapy, psychotherapy and specific cause treatment in the long run play the most important role in any program in which pain is the center of interest.

These are some of the important questions demanding consideration before one writes a single word of a prescription for the treatment of pain. We must not pretend, of course, that a clearcut answer will be always forthcoming, but I feel sure that if we ask those questions often enough we shall obtain a sufficient number of answers to make this sort of procedure extremely profitable.

Here is a list of the more common analgesic agents. It is not possible to make an altogether satisfactory classification of them. Perhaps this is as good as any, but you may think of a better one. The first group includes those agents which raise thresholds at the centers and block the perception of pain. The second includes those which relax smooth muscle and in that way abolish the impulses at their source. The third group includes substances which exert a specific action on certain kinds of pain: trichlorethylene, ergotamine, caffeine, vitamin B<sub>1</sub>. In some of these the mechanism is quite well established, in the case of others our knowledge is imperfect.

The more common clinical varieties of pain which present special problems are (1) headache, (2) visceral pain, (3) cardiac pain, (4) neuralgias, (5) root pains, (6) chronic arthritis, (7) dysmenorrhea, (8) labor pain. The list is not complete. We do not have the time this morning to go into all of these matters. Dr. Wolff is going to discuss some of the types of pain, and if any one has any special interest in others a discussion may be provoked by asking questions.

DR. CATTELL: Dr. Wolff will now take up the management of a specific type of pain.

DR. HAROLD G. WOLFF: I am going to discuss one type of pain, and that is headache; and just one variety of headache, namely migraine. I am selecting migraine to talk about for two reasons: 1. It is said to be the commonest clinical entity that civilized man happened to fall heir to. 2. I think that the management of migraine headache allows us to discuss the clinical approach to the problem of pain in general.

By migraine headache I mean the type of headache that is usually unilateral in onset, may become generalized, is associated with nausea and vomiting, sometimes with visual and other sensory disturbances, and usually occurs in families.

There are three ways of approaching this type of headache, as there are for other types of pain: first, by considering agents or procedures that act at the site of production of pain, for instance ergotamine tartrate, ergonovine, ephedrine, benzedrine, epinephrine, solution of posterior pituitary, ice cap, surgical ligation, resection and mechanical pressure; second, agents or procedures that act by raising the threshold of pain as, for example, codeine, morphine, acetylsalicylic acid, aminopyrine, acetanilid, phenacetin, ice cap; third, agents or procedures that act by lowering the blood pressure as in the case of glyceryl trinitrate or acetylcholine. I will disregard this third classification and limit our discussion to the first two.

Migraine results from the distention of some of the cranial arteries, chiefly the branches of the external carotid artery.

We know from our studies in the laboratory that a generalized headache can be produced with histamine, but after resection of the first division of the fifth cranial nerve such a headache will not appear in the part of the patient's head innervated by this division of the fifth nerve. Thus for clinical purposes we may consider the chief afferent pathway for headache to be the first division of the fifth nerve.

The method of investigation was as follows: The patient with a headache is put on a stretcher in a darkened room and a tambour over his temporal artery on the affected side records the amplitude of pulsations of the arterial walls. Records are made on a moving film in a camera.

In a representative patient with a migraine headache, ergotamine tartrate was given intravenously, and in the course of the next ten minutes the pulsations of the branches of the external carotid as recorded from the temporal artery had been reduced by 50 per cent and the headache had disappeared.

In another patient who received ergotamine tartrate (0.5 mg. intravenously) it happened to take about forty minutes for the headache to disappear, but again a parallel between the decline in the amplitude of pulsations of the temporal artery and intensity of the headache was demonstrated. A photograph was taken of this patient during the period of his headache, showing the large temporal vessels, both arterial and venous, standing out, which was in striking contrast to the flattened appearance of these vessels in a photograph taken immediately after the ergotamine had had its effect.

Records of pulsation of the cerebrospinal fluid, which represents the activity of the major spinal and the intracranial vessels, show variations in the height of pulsation which do not appear to be correlated with the headache or the disappearance of the headache after administration of ergotamine tartrate. Similarly, we have been able to demonstrate no correlation between the pressure of the spinal fluid and the headache. Thus I think we are at the moment justified in saying we do not know what role the branches of the internal carotid artery play in migraine headache, but such evidence as we have indicate it is not too important a role.

Photographs were taken of the retinal vessels before and after the administration of ergotamine tartrate. Although the veins appear to be a little smaller, I doubt whether there is much change in the arteries, although there may be a slight constriction.

Further, it can be demonstrated that ergotamine tartrate does not act in terminating headache by raising the threshold to pain. For instance, in one patient who had had his headache terminated by an intravenous dose of ergotamine tartrate an injection of 0.1 mg. of histamine produced the usual acute, the short-lived, histamine headache. This then indicates that the patient is just as able to perceive the headache after the administration of ergotamine as he was before.

In one patient the intramuscular injection of solution of posterior pituitary caused the headache to disappear, but the patient was white, was tremulous, complained of bad abdominal cramps and bad precordial pain, and I feared he might faint during the experiment. It is not a drug that one would care to give regularly, and it is not one that one can count on having a constant effect. It is not to be recommended.

Ephedrine sometimes succeeds in improving or eliminating a migraine headache, via the same mechanism: a reduction in the amplitude of pulsation of the cranial arteries. But the patient to whom it is given for migraine headache becomes tense and tremulous, and the disappearance of pain is often transient since at the end of four hours the headache may return with full intensity. Therefore, ephedrine cannot be considered as either a practical or a useful means of treating migraine headache.

In our experiments ergonovine, when successful, also eliminated headache by the same mechanism as did ergotamine tartrate. It contains more of the oxytocic property of the ergot drug, will abolish headaches in only about 50 per cent of trials, and cannot be relied on to be 100 per cent effective in reducing the amplitude of pulsations of cranial arteries.

Thus, if the agent employed succeeds in reducing the amplitude of pulsation of the cranial arteries by a sufficient amount, i. e. from 40 to 50 per cent, headache will be completely abolished, as is the case with ergotamine tartrate. It is thus evident that ergonovine hydracrylate cannot be regarded as an important asset in the treatment of migraine headache. Benzedrine sulfate, caffeine with sodium benzoate and pitressin are likewise unreliable in their effect on the magnitude of cranial artery pulsations and consequently in their effect on the headache. For instance, in two patients, caffeine with sodium benzoate (0.5 mg. intravenously) happened to increase the amplitude of pulsations and made the headache worse. Ergotamine tartrate subsequently reduced the pulsations by 40 per cent and eliminated the headache. Similarly, benzedrine sulfate reduced the amplitude of pulsations in another patient 25 per cent without reducing the headache, whereas ergotamine tartrate subsequently administered terminated it, and the amplitude of pulsations was seen to be reduced by 50 per cent. Ergotamine tartrate may at the moment be regarded as the most effective agent we have in reducing the amplitude of pulsations of the cranial arteries and terminating the migraine headache attack.

Before ergotamine tartrate was available, codeine was the best agent for stopping headache. One grain, or 60 mg., of codeine will stop most headaches, but how does it work? We observed a patient with migraine headache to whom 60 mg. of codeine was administered subcutaneously. As the headache disappeared the amplitude of pulsation of the cranial arteries did not change at all, an illustration that codeine does not act on the local pain-producing mechanism but raises the threshold to pain impulses arising from the stretched and dilated cranial vessels.

Codeine administered to another patient abolished his headache, again with no change in the amplitude of cranial artery pulsations. This patient soon complained that his headache had returned with about 50 per cent of its original severity. We then gave him ergotamine tartrate, the headache disappeared promptly, and the cranial artery pulsations, although they had not changed during this whole period when the headache had been transiently relieved by codeine, were now reduced in amplitude by over 50 per cent. His migraine attack proved to be successfully terminated.

How should one manage an acute migraine attack? The patient should retire to a darkened room and remain in bed for at least two hours, and 0.5 mg. of ergotamine tartrate should be given intramuscularly as soon as it is feasible to give the drug after the onset of the headache. This drug when given intravenously will produce quicker results; that is, it takes about thirty to fifty minutes to produce effects through the intramuscular route and about ten to forty minutes by the intravenous route. Giving ergotamine tartrate by the mouth should be avoided for two reasons: 1. It eliminates the headache only about 50 to 60 per cent of the time. 2. Patients may be induced to take it too often. Patients may have the tendency to take a few pills by mouth "every once in a while." If it is necessary to give it by mouth for reasons best known to you at the time, give 3 mg. followed by 2 mg. an hour until the headache has disappeared or a total of 11 mg. has been given. However, I am not enthusiastic about this procedure.

Suppose the patient feels as though he is about to have a migraine attack, is there anything you can do

to stop it from developing? Usually not, but you might try. The patient can be urged to go to bed and 3 mg. of ergotamine tartrate may be placed under the tongue. This will be absorbed in a few minutes and sometimes will stop the headache when repeated in 2 mg. doses hourly until 11 mg. has been given. If it does not, you are in a dilemma because you have already given ergotamine tartrate and you do not know how much more to give by the more successful intramuscular or intravenous route. I am not in favor of ergotamine tartrate by mouth. Some report the successful use of a mixture of acetanilid and sodium amytal, although I never used it and I do not know how effective it is. In any event the patient should stay in bed for two hours after such medication. Many times patients feel they are going to get a headache and don't, so you never know whether this kind of procedure is efficient or not, but you can try it and see what happens.

Don't give ergotamine tartrate more often than once a week to patients with cardiovascular disease, with or without hypertension, including those with Raynaud's syndrome, venous thrombosis, syphilitic arteritis and coronary disease; to patients with sepsis or fever; to patients with hepatic or renal disease; to pregnant women. Fortunately, most pregnant women stop having migraine attacks during their pregnancy, and the occasional woman can take ergotamine late in the pregnancy without danger; but never give ergonovine hydracrylate under any circumstances to a pregnant woman. Lastly, do not give ergotamine tartrate to badly nourished or cachectic persons. It is said that persons deficient in vitamin C do badly with ergotamine, and a poorly nourished person probably has such a vitamin deficiency. Finally, remember that in treating migraine headache you are treating the acute episode of pain and not the syndrome of migraine.

STUDENT: What is the length of time that a patient with migraine gets relief from one injection of ergotamine?

DR. WOLFF: It terminates the attack. Attacks usually last from a few hours to a few days. The administration of ergotamine does not shorten the interval between attacks. The management of the frequency of these various attacks must be through other means than ergotamine. Ergotamine simply terminates any given attack.

STUDENT: I should like to know the mode of action and effectiveness of trichlorethylene.

DR. WOLFF: Trichlorethylene is useful in pains of the face of any kind. It is not known what the exact site of action is, but it seems to raise the threshold for all types of pain about the head. Its chief usefulness is in trigeminal neuralgia. I think that was discovered, as you probably know, during the war when it was used as a solvent for certain airplane coverings, and the workers in the airplane factories were being poisoned, so that they became anesthetic about the face.

STUDENT: Has it any effect on pains elsewhere?

DR. WOLFF: I do not believe so but I am not certain.

DR. CATTELL: In the past we have been fortunate in having the collaboration of representatives from various clinical departments in connection with our conferences. The list that was put on the board by Dr. Gold includes a number of conditions which might be discussed further. I wonder if there is any one here from the Department of Obstetrics and Gynecology who might be willing to say something about the topics

dysmenorrhea and labor pain. The question of arthritis is another important topic.

DR. ANDREW A. MARCHETTI: I will talk about the first one. Dysmenorrhea is the pain in menstruation. As you know, dysmenorrhea is either congenital, functional or acquired. I think that of course the most important thing to do is to find out what can ease dysmenorrhea. Most of the time our therapy is pointed toward patients with dysmenorrhea who have either hypoplastic, that is, more or less infantile, generative organs or a malposition, acute antelexion and acute retroflexion. In those instances we give them so-called compound powders of atropine and codeine. Each powder contains 16 mg. of codeine sulfate and 0.25 mg. of atropine sulfate, as well as 160 mg. of acetylsalicylic acid and acetophenetidin. Patients are usually instructed to take the powders every four hours when they expect the pain, and usually two or three will relieve pains which are associated with the menstrual period. In instances we have used codeine, but as a rule that does not do as well as the compound powders of atropine. As Dr. Gold pointed out, the atropine is supposed to bring about relaxation of smooth muscle. It does help, especially in case of acute antelexion. It is not 100 per cent effective, of course, and it is less effective in the patient with a hypoplastic uterus.

Some of the nitrites have been used for dysmenorrhea, but I do not believe they are used as commonly as atropine and codeine.

In the acquired dysmenorrhea it may be a uterine or ovarian tumor, an inflammatory disease or a flare-up of salpingitis which causes the pain. Peritoneal or abdominal tumors that press on the uterus itself cause pain which is not elicited until the patient is about to have a period. A uterine or ovarian tumor may cause pain in the intermenstrual period.

Then too the cachectic or the undernourished person may complain of dysmenorrhea. You will find them anemic, and when they are built up by good food, fresh air, and the things we commonly have at our disposal for nutritional disturbances, usually the pain at menstrual time disappears.

Are there any questions that you wish to ask?

DR. GOLD: I wonder how deep is the conviction with regard to atropine for easing menstrual pain. A quarter of a milligram is a mighty small dose, and I am not sure that with such a dose it will be ever possible to demonstrate any physiologic effect.

There is a question I should like to ask as to codeine.

Are you ever worried about the possibility of drug addiction since these patients take it repeatedly over long periods of time?

DR. MARCHETTI: I have never seen that. I know Dr. Kelly in Baltimore is very apprehensive about drug addiction. I asked him about it and he said he had never seen it except on one or two occasions when patients became addicted to codeine. The drug is only a temporary measure. Usually, if the dysmenorrhea is severe enough, whether it is acquired, functional or congenital, the patient comes back. In the malpositions, let us say, we insert a pessary and give the patient a therapeutic test. If the retro position is relieved by putting the uterus in its normal position or approaching that, we then know the cause of the dysmenorrhea and eventually the patient will get a suspension.

DR. GOLD: I understand that aminopyrine is widely used in dysmenorrhea. Would you care to comment on this?

DR. MARCHETTI: We discourage its use, particularly because of the danger of agranulocytosis. It does relieve the pain but not as effectively as the compound powder of atropine and codeine.

DR. CATTELL: We have a small amount of time remaining for discussion, and there may be questions relating to some of the specific conditions mentioned. It seems to me this is an unusual opportunity to ask questions of men who have given special thought to the particular problems under discussion, and we should like to have all the students participate.

STUDENT: I have heard of the use of benzyl benzoate in dysmenorrhea, and I was wondering whether there was anything to it.

DR. MARCHETTI: It helps in some instances. I do not think it is as effective as the codeine and atropine.

STUDENT: I should like to ask Dr. Gold how large a dose of morphine may be given to control pain in coronary thrombosis.

DR. GOLD: You cannot give more than a quarter of a grain of morphine ever entirely safely. One gives as high as three quarters of a grain or even a grain, but if so one may expect to get into serious difficulties at times because coronary thrombosis is a classic illustration of very severe pain which tends to descend from its peak rather abruptly. If you give a quarter of a grain and the pain is not relieved, then within a half to three quarters of an hour you give another quarter and another quarter; perhaps by the third or fourth dose the pain may subside rather abruptly and at the same time you have a patient in fairly deep narcosis, in whom the pain had previously served as the antidote to the toxic effects of the morphine.

DR. CATTELL: I should like to ask Dr. Angevine whether there are some points in the management of arthritis that it might be profitable to discuss.

DR. D. MURRAY ANGEVINE: I think practically every drug has been used in the treatment of arthritis. I will mention just two types, rheumatoid arthritis and osteo-arthritis. The latter is apparently not related to infection. The ideal treatment for arthritis, just as for rheumatic fever, is rest. Sometimes it is impossible to provide rest, so we must do the best we can. We find that salicylates are of value in arthritis, but I think that is a rather general statement. We all use them because we know of nothing better, but practically 60 per cent of the patients that I see in the clinic will say "I took aspirin, but it did not help me." Rheumatic fever, of course, is an entirely different proposition. Our big agent for the treatment of arthritis, aside from rest, is physical therapy, and there are numerous methods by which it can be applied.

There are two points that may be of interest. It has been observed that patients with rheumatoid arthritis who became jaundiced become free from pain. This has been applied experimentally and about one half of the people who are jaundiced artificially are free from pain. It is obvious that such a method cannot be generally applied. However, such an observation is of value in that it may give us an indication as to the mechanism of pain in arthritis. In view of Dr. Wolff's statement that pregnancy relieves migraine it is of some interest that in a series of thirty pregnancies in patients with rheumatoid arthritis practically all were relieved of pain during their pregnancy. In fact, one woman said that she had gone through four pregnancies, and during them she was entirely relieved of her arthritis.

DR. ARTHUR P. RICHARDSON:<sup>1</sup> Pain is, of course, without a doubt the principal reason for patients coming to doctors. It is the thing that patients usually want to be relieved of. They are not particularly interested in what the mechanism is, all they want is relief from their pain. I am not at all sure of the quotation of Pasteur, but I believe it runs like this: "We would cure few, relieve many, and comfort all." That is beyond doubt the outstanding duty of all doctors, at least from the point of view of the patient.

DR. JOSEPH C. HINSEY: I have been concerned with mechanisms involved in pain rather than with drug effects on pain. However, I have been very much interested in this discussion. There are two or three points that occur to me. First, in the use of drugs which raise the threshold to pain, we are dealing with effects on peripheral or central mechanisms, and probably both. It should be emphasized that the peripheral pathways traverse the dorsal roots of spinal nerves and the sensory roots of cranial ones. There are no afferent pathways aside from these.

In dealing with drugs which attack the efferent nervous mechanisms or smooth muscle directly, the phenomenon of relaxation of smooth muscles is a very important factor in the relief of pain. In Dr. Wolff's description of the relief of migraine by ergotamine tartrate and other drugs, the pulsations in the branches of the external carotid artery were reduced. I do not know what changes in the state of the smooth muscles of the arterial walls accompanied this reduction. However, in conditions in which pain is produced by anemia and the resultant anoxia in tissues, relaxation of smooth muscle in the vascular bed induced by the action of drugs leads to an improvement of blood supply and helps to relieve pain. In physical therapy, counter-irritation may relieve pain by the induction of reflexes that relax smooth muscle both at the periphery and in the viscera, producing among other things an improvement of blood supply.

Second, there is one other place where drugs are used in the problem of pain that is of interest at the present time; that is, in the field of diagnosis. The use of local anesthetics in the blocking of peripheral and visceral nerves gives information as to the possible relief to be obtained in painful syndromes by surgical procedures. Recently, Livingston has reported ten cases of atypical pain in the extremities produced by trivial injuries. He found that he could relieve pain by the use of local anesthesia at the periphery in the "trigger" zones and also by blocking the sympathetic trunks. It seems to me that the use of local anesthetics such as procaine hydrochloride has an important role in the attack on a number of types of atypical pain.

**Political Career of Claude Bernard.**—The year 1860 saw the beginning of Bernard's political career, which was, indeed, short but which occurred at an exciting moment in the history of his country. An imperial decree of May 6 made him a senator. His yearly income was in consequence augmented by 30,000 francs and there is still among his relics at Saint-Julien a card bearing five stamps, which shows that he received five quarterly payments of his stipend. . . . Bernard took his duties as senator seriously, as he did all obligations which he assumed. There is not a day's balloting recorded in the official journal after Bernard took his seat in August 1869 which does not include his name.—Olmsted, J. M. D.: Claude Bernard, Physiologist, New York, Harper & Bros., 1938.

## Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION OF THE FOLLOWING ARTICLE AND REPORT.

HOWARD A. CARTER, Secretary.

### PHYSICAL CHARACTERISTICS OF SHORT WAVE DIATHERMY

ALLAN HEMINGWAY, PH.D.

AND

K. W. STENSTROM, PH.D.

Assistant Professor of Physiologic Chemistry and Professor of Biophysics,  
Respectively, University of Minnesota

MINNEAPOLIS

In former articles<sup>1</sup> the physical and biophysical aspects of the older type of long wave diathermy have been discussed. These previous articles contain descriptions of the methods whereby the low frequency 25 to 60 cycle alternating current may be converted into high frequency diathermy current by means of the spark gap diathermy machine or the vacuum tube apparatus. This older type of diathermy current is that which has a frequency between 500 and 2,000 kilocycles per second and is applied to the patient by contact electrodes. Since a discussion of long wave diathermy has already been given, and since the main interest today is in short wave diathermy, the present article will be confined almost exclusively to short wave diathermy except when comparisons are to be made with the older form of diathermy.

It is of historical interest that during the past year a friendly controversy has arisen as to the priority of the discovery that high frequency alternating electric currents could traverse irritable tissues without electrical shock. The clinical use of diathermy as a mode of therapy followed soon after this discovery. According to Bordier,<sup>2</sup> d'Arsonval, Claude Bernard's successor at the University of Paris, commenced in 1881 a study of the stimulating effects of electric currents of varying frequency. d'Arsonval built an oscillator capable of producing alternating currents of frequencies as high as 10,000 cycles a second and demonstrated to his classes at the university in 1889 that at the higher frequencies the current for stimulation had to be increased. Following the discoveries of Hertz, d'Arsonval used the hertzian oscillator (the spark gap circuit) for frequencies above 10,000 cycles. These results were published in 1891 and first presented at meetings of the Society of Biology at Paris at its sessions of Feb. 24, April 25 and May 2, 1891. Nikola Tesla, an Austrian physicist in the United States, was studying illumination produced by high frequency currents and noted that high frequency currents of sufficient intensity to cause illumination did not produce neuromuscular stimulation. These observations of Tesla were published May 23, 1891. The conclusion to be drawn from this interesting note of Bordier's is that the discoveries were made almost simultaneously and were published in 1891. This year may be regarded as the beginning of the development of diathermy.

### SHORT WAVE DIATHERMY

Since 1930 there has arisen a continuously increasing interest in short wave diathermy, stimulated by many clinical reports of its beneficial therapeutic use and a large amount of advertising by manufacturers of apparatus. This new form of therapy has been greeted with much enthusiasm by some investigators as a discovery of major importance. The *British Journal of Physical Medicine*<sup>3</sup> states "It is no exaggeration to call short wave diathermy the greatest discovery in physical medicine since the work of Roentgen." Other investigators, particularly those in America, have been less enthusiastic about the merits of short wave diathermy and believe it to be solely a unique and useful method of applying heat. Conventional diathermy, or long wave diathermy, has been used with success for many years and short wave diathermy can be regarded only as a new and improved mode of therapy if it has definite proved advantages over the older type. It is our purpose in this review to describe the method of production of short wave currents and then to discuss the advantages and disadvantages of the newer form of diathermy in comparison with the older form.

### A TYPICAL OSCILLATOR CIRCUIT

There are several typical circuits for the generation of short wave diathermy currents. These may be divided into two groups: those which produce the longer of the short wave diathermy currents, i. e. frequencies in the range from 10 to 100 megacycles (from 30 to 3 meters), and a second group producing frequencies greater than 100 megacycles. As a typical oscillator of the first group, the simple two-tube "push-pull" circuit will be described. This type of oscillator for production of long wave diathermy currents (1 megacycle per second) has been described by Hemingway and Witts.<sup>4</sup> The same typical current may be used for the generation of higher frequencies.<sup>5</sup> This entire circuit can be considered to consist of three essential parts, (a) the power supply, (b) the oscillating circuit and (c) the output circuits.

(a) *The Power Supply.*—The high frequency current in short wave diathermy machines is generated by a vacuum tube oscillator circuit which usually consists of one or two vacuum tubes with an appropriate circuit of inductances and capacities. The thermionic vacuum tubes are evacuated glass bulbs containing a filament, grid and plate. The filament is heated to incandescence by a low voltage alternating current of the same frequency as the input current, i. e. from 25 to 60 cycles per second. A high direct current voltage of from 100 to 1,000 volts is applied between plate and filament, the plate being made positive and the filament negative. It is the function of the power supply to furnish the low frequency low voltage alternating current to heat the filament of the vacuum tubes and to supply the high direct current voltage to draw electrons from the filament to the plate. The power supply unit consists of one or two transformers, two or four rectifier vacuum tubes and sometimes a condenser. For simplicity a four tube rectifier will be described, but this may be

replaced by one with two tubes which functions as the described four tube type.

One transformer converts the 110 volt 60 cycle current to low voltage 4 to 10 volt 60 cycle current to heat the filament of the vacuum tubes. This is a "step-down" transformer. The other one is a "step-up" transformer and converts the 110 volt 60 cycle current into from 500 to 1,000 volt 60 cycle current. This high voltage current in some machines is "rectified," as will be described, or in other machines is delivered as high voltage alternating current to the oscillator tubes.

The rectifier system, if present, consists of two or four rectifier tubes. A four tube rectifier is shown in figure 1 and consists of four diode tubes. The two tube rectifiers function in the same manner but two tubes are combined into one. These diode tubes each contain a filament and plate and permit electrons to flow only in one direction—from filament to plate—and in this way behave as thermionic valves. An electron current flows only when the plate is positively charged with respect to the filament. When the plate is positive the negatively charged electrons which are emitted by the filament move to the plate, the stream of particles forming the current. When the filament is made positive and the plate negative no current flows, since the current through the tube is carried only by the negatively charged electrons. In figure 1 the arrows indicate the

Fig. 1.—Action of full wave rectifier in power supply unit of an oscillator. *F P*, filament and plates of rectifier tubes, 1, 2, 3, 4. *Osc*, vacuum tube in oscillator circuit to which rectifier supplies a high direct current voltage output. *Con*, condenser of high capacity connected in parallel with direct current output of rectifier. *A*, alternating current from transformer secondary as indicated in ammeter *M*<sub>1</sub>. *B*, rectified current flowing in output circuit as measured in ammeter *M*<sub>2</sub> without condenser (*Con*) in circuit. *C*, output current from rectifier as measured in *M*<sub>1</sub> with condenser (*Con*) connected as shown.

direction in which the current flows through the tubes. A high voltage alternating current is supplied to the rectifier system by the step up transformer. This current, which passes through meter *M*<sub>1</sub>, is indicated at

curve *A*. The positions *x* and *y* are subjected to an alternating potential, which varies in a cyclic manner. When *x* is positive *y* is negative and  $\frac{1}{120}$  second later *x* is negative and *y* is positive. When *x* is negative and *y* is positive the electron current flows over the path  $x \rightarrow 1 \rightarrow osc \rightarrow 3 \rightarrow y$  and no current flows through tubes 2 and 4 on account of the electronic action of the

Fig. 2.—Simple oscillator circuit. *F*, filament; *G*, grid; *P*, plate; *C*, condenser; *L*, inductance; *M*, grid meter; *A*, direct current voltage applied to plate; *A*, current.

valve. During the next half cycle when *x* is positive and *y* negative the current flows over the path  $Y \rightarrow 2 \rightarrow osc \rightarrow 4 \rightarrow X$  and no current flows through tubes 1 and 3. In both instances the current from the rectifier, that is, the current supplied to the oscillator (*osc*) and measured by meter *M*<sub>2</sub>, flows in one direction. Without the condenser (*con*) the unidirectional current from the rectifier would pulsate as shown in curve *B*. The presence of the condenser (*con*) smooths out the pulsations to give an output current as indicated by curve *C*. The condenser acts as a storage place for the electrical charges that enter and leave while rapid changes of current are taking place. This condenser has a tendency to produce a uniform flow in much the same way as that in which the elastic walls of the large arteries take up the pressure pulse and produce an even flow of blood.

(b) *The Oscillator Circuit*.—This consists of a three electrode vacuum tube containing filament, grid and plate connected in a circuit containing a condenser *C* and an inductance *L*, as shown in figure 2. A stream of electrons is drawn by the high voltage from the heated filament to the plate through the grid. The magnitude of this current is controlled by the grid voltage and plate voltage. The closed circuit containing *C* and *L* has the important property of having an alternating current produced within it under the conditions shown. The frequency of the alternating current is determined by the capacity of the con-

denser and the inductance ( $L$ ) according to the formula  $f = \frac{1}{2\pi\sqrt{LC}}$ , in which the inductance depends on the size and number of turns of the coil and the capacity ( $C$ ) depends on the distance between the condenser plates and on their areas and number.<sup>1b</sup> It is to be noted that as the capacity and inductance decrease the frequency increases. With short wave oscillators the capacity and inductance are very small. The plate and filament are made of metal. They are separated by a vacuum and behave as a condenser, which is in parallel with  $C$ . Usually this interelectrode capacity is small, but when very short wave radiation (high frequency) is to be produced it is this factor which sets an upper limit to the frequencies that can be produced. In some circuits this is the only capacity in the oscillation circuit. The oscillating current in the

$LC$  circuit induces voltage changes in the coupling inductance ( $M$ ), which are impressed between the grid and the filament and produce fluctuations of the same frequency in the plate current. This phenomenon is called the "grid feed back" and is responsible for the "regeneration" or maintenance of a sustained oscillating current in the  $LC$  circuit.

(c) *The Output Circuit.*—This circuit of the short wave apparatus contains the electrodes or coils which are applied to the patient in addition to a variable condenser, an inductance and a meter. The output circuit is represented on diagram III in figure 3, which shows an assembled short wave diathermy circuit, including the power supply (diagram I) and the oscillator circuit (diagram II). The external

tubes is shown in diagram I, where the bridge method of rectification, as shown in figure 1, is used. The leads  $A$  in figure 3 carry current to heat the filaments of the oscillator tubes 5 and 6. The leads  $B$  carry the high voltage rectified current,  $B+$  being connected to the plate and  $B-$  to the filament of the oscillator tubes. Diagram II of figure 3 shows the main oscillating circuit and its connections. This oscillating circuit is a widely used two tube oscillator type which gives added power and stability, but the principle of operation is the same as the simpler circuit of figure 2. Actually there are many modifications of this typical circuit in use today but the general scheme is the same for all. This type of machine may be used for both long and short wave diathermy current. A similar device has been described by Bishop.<sup>5</sup>

#### CHARACTERISTICS OF SHORT WAVE DIATHERMY CURRENT

(a) *Position of Electrodes.*—When long wave diathermy is used, it is necessary to place the electrodes in contact with the skin. In many treatments this is a satisfactory procedure but in some cases it is unsatisfactory, especially when a large electrode is to be used over some irregular surface in which there are bony projections. With short wave diathermy it is possible to place an insulating pad or to interpose a layer of air between electrode and cutaneous surface, or one may use a coil of fairly rigid insulating cable wrapped around a limb but at some distance from the cutaneous surface. By applying short wave electrodes at a distance, it is possible to heat the desired region without causing irritation of the skin. According to Cumberbatch<sup>6</sup> it is this characteristic of the short wave diathermy that is responsible for the beneficial effects in acute infections of the skin and subcutaneous regions. Krusen<sup>7</sup> states that the difference between the long wave and the short wave diathermy is the convenience of the short wave technic.

The reason contact electrodes must be used with long wave diathermy whereas distant electrodes may be used with the short wave apparatus is the differences in frequency between the two types. Figure 4 represents a conducting tissue between two short wave diathermy electrodes with an air space separating the tissue from the electrodes. The equivalent electrical circuit is also shown. Part of the current passes between the condenser plates as a wattless current indicated by  $I_1$ . The conduction current that heats the tissue flows through the resistance  $R$ . The system of tissue-air space-electrode at each electrode behaves as a condenser. The impedance of this condenser  $C_2$  is given by the fraction  $1/\text{frequency} \times \text{capacity}$ . The capacity may be increased by bringing the electrode closer to the tissue, since the capacity is inversely proportional to the thickness of the dielectric, in this case air. The impedance to the high frequency current may be reduced by increasing the capacity and increasing the frequency. Hence increasing the frequency allows more current to pass through this condenser and through the tissue. There is some belief that the mechanism of heating and current conduction is different in the two types of diathermy. There is no basis for this belief. The current through tissue consists of oscillating charges. Increasing the frequency causes the ionic

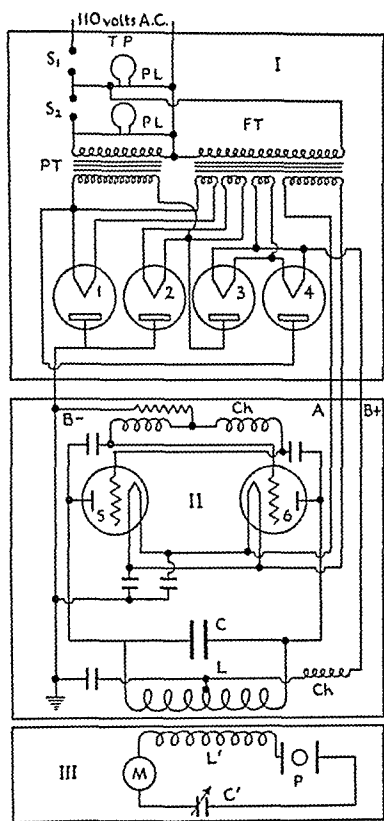

Fig. 3.—Circuit for the production of short wave diathermy current; I, power supply; II, oscillator circuit; III, output circuit;  $S_1$ ,  $S_2$ , switches;  $PL$ , pilot lamp;  $FT$ , filament transformer;  $PT$ , plate transformer; 1, 2, 3, 4, rectifier tubes; 5, 6, oscillator tubes;  $C$ ,  $L$ , capacity and inductance in main oscillating circuit;  $C'$ ,  $L'$ , capacity and inductance in external output circuit;  $M$ , ammeter for measuring current in output circuit;  $P$ , tissue heated;  $B-$ ,  $B+$ , direct current voltage to plate filament of oscillator tubes;  $A$ , low voltage alternating current leads for heating filament of oscillator;  $Ch$ , choke coil.

circuit containing the patient is inductively coupled to the main oscillating circuit  $LC$ . Current in this external circuit is increased or decreased in one of two ways, either by "tuning," i. e. varying the capacity of the output circuit, or by changing the coupling between the output circuit and the main oscillating circuit. By changing the coupling the two inductances  $L$  and  $L'$  are brought closer together, thus increasing the current in the external circuit.

The assembled circuit is shown in figure 3. The power supply, including transformers and rectifier

7. Krusen, F. H.: The Present Status of Short Wave Diathermy, J. A. M. A. 110: 1280 (April 16) 1938.

displacement to be less and the rapidity of oscillation greater. If a long wave diathermy machine were connected to short wave electrodes, with an air space between electrodes and tissue, a current would flow but it would be small because of the high impedance of the air space and would be insufficient to cause appreciable heating.

(b) *Measurement of Temperature.*—One of the reasons why so little progress has been made in determining the temperature distribution of animals or patients treated with short wave diathermy is that it is not possible to measure the temperature of a heated tissue by a thermocouple or a mercury thermometer during the passage of the current. These metallic temperature measuring devices when placed in a short wave electrical field behave as receiving antennas and foci for the short wave current. In measuring the temperature of a tissue heated by short wave diathermy the customary procedure is to shut off the diathermy current and insert the thermocouple needle into the heated tissue. In the time interval between the shutting off of the current and the final equilibrium deflection of the galvanometer a considerable fall in temperature may occur, especially in a vascular region. Using long wave diathermy to heat a vascular region of the brain of dogs and placing fine wire thermocouples between electrode and brain tissue, we have noted a drop of 3 degrees centigrade in half a minute after the diathermy current was turned off.<sup>8</sup> With long wave diathermy it is possible to measure the temperatures of the heated tissue while the current is flowing. Thermocouples may be used to measure long wave heating effects provided proper precautions are observed as to galvanometer shielding, use of choke coils and position of the thermocouple in the field, according to Stenstrom and Nurnberger<sup>11</sup> and Hemingway and Hansen.<sup>9</sup>

(c) *Measurement of Dosage.*—With long wave diathermy, clinical experience over many years has established definite dosages that are recommended for treatment. These dosages are prescribed in terms of the current density of the smaller diathermy electrode, with 100 milliamperes per square inch of the smaller electrode recommended as the maximum. If the diathermy current passes through a constricted region smaller than the area of the smaller electrode, this dosage must be reduced, as, for example, heating through a knee joint with electrodes above and below the knee.

For many years it was believed that the diathermy current measured by the meter of the long wave machine was not a true heating current. It was believed that a part of the current registered by the ammeter was "wattless" in that it did not produce heat within the tissues. It is theoretically possible that a current passing through the tissues between diathermy electrodes should have a "conduction" component which is responsible for the heating and a "wattless" component which passes across the electrodes as through a condenser, the so-called displacement current. d'Arsonval<sup>10</sup> made measurements of the heat production in solutions heated by long wave diathermy and stated that a large fraction of the total current

was wattless. The significance of this observation by d'Arsonval was that it made dosage measurements of long wave diathermy impossible, since a dosage stated in milliamperes per square inch would be useless if a large fraction of the current was wattless. This problem was reinvestigated by Hemingway,<sup>11</sup> and measurements were made of the resistance and phase angle by Hemingway and McClendon<sup>12</sup> of tissues heated by long wave diathermy. It was shown that under clinical conditions the current as registered by the diathermy ammeter was almost entirely conduction current, the wattless component being negligible. In the highest frequencies of the long wave diathermy region, e. g. 2 megacycles per second, the wattless component could be 5 per cent of the total diathermy current.

With short wave diathermy it is not possible to designate dosage in terms of diathermy current which would be applicable to all types of treatment. The reason for this is that as the frequency increases from the long wave range, 0.5-2.0 megacycles per second, to the short wave range, 10-100 megacycles per second, the wattless component of the current increases. The wattless component is increased still more when the electrodes are used at some distance from the skin

Fig. 4.—Electrical equivalents of tissue between short wave diathermy electrodes.

and varies with shape, size and position of the electrodes. The dosage must be regulated by experience as judged by the sensation of heat in the patient. Once a dosage calibration on this patient's tolerance basis has been established one can assume that for a given position, size and shape of electrode and shape, size and position of the region of the body heated the wattless component remains the same and that the electrical conditions can be repeated.

(d) *Temperature and Heat Distribution.*—1. Experiments on Solutions and Dead Tissues: A striking characteristic of short wave electrical fields is that, when the field intensity is kept uniform and electrolytic solutions of various concentrations in test tubes are placed in the field for the same length of time, the rate of heating for the different solutions varies. This effect as described by Hosmer<sup>13</sup> has been verified by others and shown by McLennan and Burton<sup>14</sup> and Pätzold<sup>15</sup> to be a direct consequence of the physical laws governing the heating of electrolytic solutions. According to

electromagnetic theory, and supported by experimental observations, the rate of heating of a solution in an electrical field between the electrodes of a short wave diathermy machine depends on the frequency (or wave length) of the alternating electrical field. At a particular frequency, the rate of heating is a maximum. The frequency at which the maximum heating takes place is related to the electrical conductivity and dielectric constant by the formula

$$\text{frequency} = \frac{2 \times \text{specific conductivity}}{\text{dielectric constant}}$$

The various tissues of the human and animal body have specific conductivities which vary widely.<sup>16</sup> Schereschewsky<sup>17</sup> has shown, however, that the dielectric constants of different tissues are practically equal to that of water, 76-78, with the exception of fat, which has a low value of 13.6. The theory would predict that different tissues with these widely varying electrical conductivities would each have a certain specific wavelength at which maximum heating would take place in the high frequency fields. That such maximum heating effects for various tissues do actually occur have been shown by Schereschewsky,<sup>17</sup> McLennan and Burton,<sup>18</sup> Bachem<sup>19</sup> and others. These were dead tissues usually isolated from other tissues in glass containers. There is, however, a considerable lack of agreement among the various investigators as to what wavelength produces a maximum heating effect for a particular tissue. As an example, according to Coulter and Osborne,<sup>20</sup> three different investigators have reported three different wavelengths for the maximum heating of fat, namely 14.5, 3 to 10 and 5 meters. One may conclude that the maximum heating effect for a particular dead tissue does occur for a definite wavelength but that it is variable with the tissue and technic of measurement. Selective heating of a tissue for a particular wavelength has been observed in dead limbs by Schliephake<sup>21</sup> and McLennan and Burton.<sup>18</sup>

Basing these observations on these demonstrations of selective heating of dead tissues, either isolated or in situ, some authors have assumed that this selective heating action applies to tissues in living warm blooded animals. Such assumptions without experimental proof are entirely unwarranted. Those controlled experiments which have been performed for the purpose of investigating this particular problem have shown no selective action, at least in the tissues of human beings.<sup>22</sup>

2. Experiments on Living Animals and Man: As a result of the interesting studies on selective heating as a function of the wavelength of solutions and tissues in vitro, the results of temperature distribution in living tissues becomes a problem of prime importance. The

differences between dead excised tissues and living tissues in situ are that: 1. There is in the living body a powerful equalizing action exerted on the tissue temperature by the circulating blood. The importance of this was well demonstrated by Binger and Christie<sup>23</sup> for long wave diathermy. These investigators showed that the circulation through a locally heated region tended to reduce any local rise in temperature. 2. A tissue in situ is in contact with and surrounded by other tissues. These neighboring tissues, which may be good conductors, such as muscle and plasma, tend to exert a "shielding" effect. The heating of a particular tissue such as bone in a living animal is quite a different problem from the heating of bone in a test tube surrounded by glass or air. The measurements of Mortimer<sup>24</sup> have indicated the importance of the equalizing effect of blood flow on temperature of the visceral organs of dogs heated by short wave diathermy. Mortimer and Osborne,<sup>22</sup> Coulter and Carter<sup>25</sup> and Coulter and Osborne<sup>25</sup> have measured the increase in temperature at various sites in human subjects, using short wave diathermy currents of wavelengths from 6 to 24 meters, and have reached the conclusion that there is no specific or selective heating shown that varies with the wavelength. It would seem from their work that one wavelength is as good as another.

#### CONCLUSION

We wish to emphasize the need for more investigations on the controversial problems, especially the so-called athermic effects. More work is needed on the temperature distributions in various living tissues and the development of better methods of thermometry for temperature measurements during the course of a treatment.

Of particular interest is the development of vacuum tubes capable of producing even shorter radiations than those used in therapy at present. The radiation from these oscillators is of the order of centimeters instead of meters, and such radiation has more pronounced optical properties than the radiation of the short wave field. This 1 to 100 cm. wavelength radiation may be focused<sup>26</sup> and directed along tubes.<sup>27</sup> These properties would seem to indicate that it would be particularly valuable in that the beam could be directed to a desired region. It would be of interest to know the absorption coefficients of this radiation and the extent of their dependence on wavelength and type of tissue. The newer tubes being developed are of the Magnetron type<sup>28</sup> or have resulted from newer designing of the more conventional negative grid tube.<sup>29</sup> It may be that many of the older problems and controversies that have marked the development and final utilization of long wave diathermy and short wave diathermy will reappear when these newer tubes are available for therapy and experiment.

**HOGAN ADVANCE MODEL BREVATHERM,  
MODEL #8640, ACCEPTABLE**

Manufacturer: McIntosh Electrical Corporation, 233 North California Avenue, Chicago.

The Hogan Advance Model Brevatherm, Model #8640, is a portable short wave diathermy unit. It may be used for medical diathermy and for minor surgery. It is available with a mobile walnut or ivory finished cabinet, Model #8645. Standard accessories include one set of pad and one of cuff electrodes.

Hogan Advance Model Brevatherm, Model #8640.

Optional accessories consist of inductance cable and electrosurgical instruments.

The vacuum tubes in a tuned plate, tuned grid, push-pull oscillator circuit generate high frequency energy at a wavelength of approximately 12 meters. The output circuit for the cuff and pad electrodes is inductively coupled and the circuit for the cable is capacitatively coupled to the plate circuits of the oscillator.

The firm claims that the unit has an output of 240 watts as measured by a lamp load, photoelectric cell and wattmeter at a voltage of 116.5. The Council's investigator confirmed these claims. Transformer temperature rise and the temperature rise at various levels within the cabinet after a two hour run at full load were within the limits of safety prescribed by the Council.

The firm submitted thirteen tests, performed by a reliable investigator, as evidence of the unit's ability to produce heat deep in human tissues. The deep muscle temperatures were taken at a depth of about two inches, that is, the full length of the needle was inserted when the size of the leg permitted it. In other cases, the needle was inserted to the bone. A Leeds

Schematic Diagram of Circuit

Northrup Potentiometer was used as well as hypodermic needle thermocouples, in taking the temperatures. All determinations were run first on the right leg, then on the left. In all determinations the time interval between two successive tests on the same leg was never less than one-half hour. The time of

*Averages for Seven Observations, Cuff Technic*

Deep Muscle		Subcutaneous		Skin	
Initial	Final	Initial	Final	Initial	Final
98.1	106.2	94.3	102.7	87.9	92.3

*Averages for Six Observations, Coil Technic*

Deep Muscle		Subcutaneous		Skin	
Initial	Final	Initial	Final	Initial	Final
98.7	104.9	93.5	103.5	91.8	94.0

application was twenty minutes for each treatment. Room temperature ranged from 75 to 83 F. and the humidity varied from 62 to 70 per cent during the test periods.

Seven tests were made in which the cuff technic was used. The thigh was covered with three thicknesses of flannel and one of toweling, topped with a five-eighths inch strip of felt. The distance between cuffs was from 7 to 9 inches.

Six tests were carried out with the cable technic. A towel was first wrapped around the thigh single thickness and one-half inch felt strips were inserted between the coil and the towel.

The unit was investigated for the Council in a reliable clinic, where it was used for several months for general clinical application. It was reported a satisfactory unit.

In view of the foregoing report, the Council on Physical Therapy voted to accept the Hogan Advance Model Brevatherm, Model #8640, for inclusion in its list of accepted devices.

## Council on Foods

### ACCEPTED FOODS

THE FOLLOWING PRODUCTS HAVE BEEN ACCEPTED BY THE COUNCIL ON FOODS OF THE AMERICAN MEDICAL ASSOCIATION AND WILL BE LISTED IN THE BOOK OF ACCEPTED FOODS TO BE PUBLISHED.

FRANKLIN C. BING, Secretary.

### BAKER'S MODIFIED MILK, POWDERED AND LIQUID FORMS

Manufacturer.—Baker Laboratories, Cleveland.

**Description.**—Powdered form: A spray-dried homogenized mixture of evaporated skimmed milk, whole milk, lactose, coconut oil, beef fat, dextrose, cod liver oil and gelatin with added wheat germ extract and iron and ammonium citrates, U. S. P.

Evaporated liquid form: An evaporated homogenized mixture of evaporated skimmed milk, whole milk, lactose, coconut oil, beef fat, dextrose, cod liver oil and gelatin with added wheat germ extract and iron and ammonium citrates, U. S. P.

**Manufacture.**—Powdered form: The milk used is produced by tuberculin tested herds from an accredited area inspected by representatives of the Chicago Board of Health and is regularly inspected at the factory for quality and sanitation. Formula proportions of lactose, dextrose, coconut oil, beef fat, gelatin, cod liver oil, wheat germ extract and iron and ammonium citrates, U. S. P., are added to definite amounts of evaporated skimmed milk and whole milk. The mixture is pasteurized, homogenized, spray dried, packed into cans and hermetically sealed.

Evaporated liquid form: The milk used is the same as for Baker's Modified Milk, Powdered Form. Formula proportions of lactose, dextrose, coconut oil, beef fat, gelatin, cod liver oil, wheat germ extract and iron and ammonium citrates, U. S. P., are added to definite amounts of evaporated skimmed milk and whole milk. The mixture is pasteurized, homogenized, evaporated to a standard total solids content, filled into cans, sealed and heat processed.

**Analysis** (submitted by manufacturer).—Powdered form: moisture 1.4%, total solids 98.6%, ash 2.9%, fat 24.8%, protein (N  $\times$  6.38) 15.0%, carbohydrates (by difference) 55.9%. Liquid form: moisture 75.0%, total solids 25.0%, ash 0.8%, fat 6.4%, protein (N  $\times$  6.38) 3.8%, carbohydrates (by difference) 14.0%.

**Calories.**—Powdered form: 5.06 per gram; 144 per ounce. Liquid form: 1.28 per gram; 36 per ounce.

**Vitamin.**—Vitamin D: Powdered form, 3.9 U. S. P. units per gram; liquid form, 0.41 U. S. P. units per gram. Both powder and liquid forms supply not less than 400 U. S. P. units of vitamin D per quart, when diluted to "normal" strength as directed on the label.

### MRS. PALEY'S BABY FOOD—STRAINED EVAPORATED PRUNES

Manufacturer.—Paley-Sachs Food Company, Houston, Texas.

**Description.**—Cooked, sieved dried prunes.

**Manufacture.**—Dried prunes are washed, soaked for twelve hours, precooked in air-tight pressure cookers, automatically pitted, sieved, filled into glass jars, vacuum sealed and heat processed.

**Analysis** (submitted by manufacturer).—Moisture 68.3%, total solids 31.7%, ash 0.6%, fat (ether extract) 0.1%, protein (N  $\times$  6.25) 1.0%, reducing sugars as dextrose 17.1%, sucrose 0.6%, crude fiber 0.6%, total carbohydrates other than crude fiber (by difference) 29.4%, calcium (Ca) 0.026%, phosphorus (P) 0.034%, iron (Fe) 0.002%.

**Calories.**—1.2 per gram; 34 per ounce.

## MODE OF ACTION OF SULFANILAMIDE

Apparently sulfanilamide possesses a specific chemotherapeutic effect on the beta-hemolytic streptococcus; it is of low toxicity, is easily administered, is quickly absorbed and is more effective in vivo than in vitro. The results obtained in the treatment of puerperal sepsis (Colebrook and Kenny) and in hemolytic streptococcus meningitis (Long and Bliss) are sufficiently dramatic to warrant the enthusiasm aroused by this new chemotherapeutic agent. Its administration in man is associated with definite though not necessarily unavoidable or serious hazards. In a recent communication, Long and Bliss<sup>1</sup> analyze toxic manifestations which have occurred during the course of treatment with sulfanilamide in 335 cases at the Johns Hopkins Hospital. The most common toxic effects manifested were dizziness, headache, a loss of ability to concentrate, anorexia, nausea and, in some instances, vomiting. Cyanosis of varying degrees was almost constant. This is said by some observers to be due to sulf-hemoglobinemia, by others to methemoglobinemia. Clinical acidosis as evidenced by combination of hypernoia and a lowered carbon dioxide combining power has been noted in 3 per cent of the cases. Jaundice occurred in only one case. Dermatitis occurred in 1 per cent and was apparently associated in one case with photosensitivity of the skin. Simple fever has been the most common toxic reaction noted (6 per cent). An early febrile response was likewise noted in all cases in which dermatitis, acidosis, acute hemolytic anemia or agranulocytosis developed. Anemias of the hemolytic type have occurred quite commonly and in 3 per cent of the cases were of the severe type characterized by a rapid fall in the red blood cell count in the hemoglobin, leukocytosis, reticulocytosis, bilirubinemia, urobilinuria and, in certain instances, porphyrinuria. Other authors have reported cases of agranulocytosis with occasional fatal results. Thus the most serious toxic manifestations are those associated with the blood

or hematopoietic system. The mechanism of this type of anemia is not clearly understood, but it would seem to be the result of an idiosyncrasy toward the drug.

Thus in sulfanilamide we have a potent chemotherapeutic agent for combating certain types of invasive bacterial disease. The precise mechanisms of its action on bacteria, as well as its toxic effects, have not been clearly elucidated. Progress is to be anticipated from the experimental studies rather than from the empirical observations of the clinic. A more or less scientific basis for the therapy of sulfanilamide was made possible through the experimental studies of Marshall and his co-workers.<sup>2</sup> They have developed a simple biochemical method for the quantitative demonstration of sulfanilamide in blood and in urine and have pointed out the importance of determining the concentration of the drug in the blood of patients undergoing treatment. Following a single oral dose, the drug is absorbed in about four hours. It is almost entirely excreted in the urine. By repeated dosage of the drug at intervals of four hours an equilibrium can be established between ingestion and elimination and the drug maintained at a definite concentration in the blood and tissues. These observations have been of the greatest importance in establishing a rational basis for therapy in infected human beings. Lockwood<sup>3</sup> demonstrated that the concentration of the drug in the amount of 10 mg. per hundred cubic centimeters of whole blood prevented the multiplication of young virulent streptococci in test tube experiments. Lockwood and his colleagues<sup>4</sup> similarly conclude in this issue of THE JOURNAL that the striking effect of sulfanilamide is a depression of the invasive properties of the organism. The optimum level for treatment in severe cases seems to lie between 5 and 10 mg. per hundred cubic centimeters of blood. Colebrook and his co-workers found sulfanilamide to be bactericidal against hemolytic streptococci in vitro and to a lesser degree in vivo. They did not, however, fail to observe the discrepancy between the striking therapeutic results obtained and the limited bactericidal effect in vitro. They concluded that the effect was the result of the combined bactericidal action of the blood plus that of the body tissues of the animal. Mellon, Cross and Cooper<sup>5</sup> found in their experiments that both sulfanilamide and its derivatives exhibited therapeutic effects in mice against hemolytic streptococcus infections. They found no indication that phagocytosis is a factor in the mechanism of the therapeutic action of these drugs. Likewise they failed to find qualitative changes in the character of the histologic response

to the hemolytic streptococcus as the result of the administration of sulfanilamide, Lockwood found that normal serum without leukocytes is just as effective *in vitro* as a vehicle for the action of sulfanilamide in inhibiting the growth of streptococci. Lockwood found that addition of peptone to the serum in his experiments diminished the ability of sulfanilamide to restrict or to retard the growth of streptococci. He therefore concluded that the drug interferes with the ability of virulent hemolytic streptococci to use serum protein as a food from which to obtain nitrogen.

Most observers agree that the addition of sulfanilamide to nutrient broth or human serum slows the rate of multiplication but does not lead to the destruction of beta-hemolytic streptococci. The action of the drug, however, is not completely explained by this bacteriostatic influence, since it was proved that it enhances the bactericidal powers of human blood in infected patients. Lyons<sup>6</sup> found that sulfanilamide rendered human virulent strains of hemolytic streptococci more susceptible to the bactericidal action of human blood and that this effect is reversible on withdrawal of the drug. He found that in certain types of sustained hemolytic streptococcus bacteremias it was necessary to add an antibacterial antibody to sulfanilamide in order to obtain a therapeutic effect. The effective therapy for this type of infection should consist of sulfanilamide and the intravenous injection of specific antibacterial antibody by the immunotransfusion technic. He concludes that sulfanilamide induces a physiochemical alteration in the antigenic structure of hemolytic streptococci which decreases the invasive capacity or virulence of the bacteria.

#### FORMATION OF MILK PROTEINS

The phenomenon of lactation is of perennial interest to the physiologist, biologic chemist and pediatrician. Not only is the period of preparation an illustration of fine endocrine coordination and balance but the actual production of milk presents an opportunity to study metabolism taking place at an unusually rapid rate. The turnover of materials incident to the elaboration of large quantities of milk may present astounding values. Some dairy cows have made records of 100 pounds of milk a day; this yield means a large consumption of feed and water. It means the annual loss by way of the mammary glands of some 150 pounds of ash, of 25 pounds of calcium, of ten times the organic matter contained in the cow's body and of more than 1,000 pounds of protein.

The product of the mammary gland for several days post partum is unusually rich in protein. This secretion, called colostrum, contains in the case of the cow about 17 per cent of protein, a large proportion of which is a globulin identical with serum globulin. Ord-

narily globulin accounts for a small part of the total protein of milk, so that this high concentration in colostrum is striking and suggestive. It has been shown that this protein, after having been consumed by the newborn calf, passes unchanged through the intestinal wall into the blood, thus providing serum globulin for the calf whose blood during early life is essentially devoid of this immunologically important constituent.

The origin of the milk proteins was early studied by Cary,<sup>1</sup> who reported a withdrawal of amino acids from the blood as it passed through the mammary gland. He concluded that the proteins of milk arose from these amino acids taken from the blood. An analysis of the blood of lactating women, however, did not show any deviation from the normal in the level of amino acids.<sup>2</sup> Other reports showed that the nonprotein nitrogenous constituents of milk and those of blood were similar in concentration, and later identical values for urea were found in these two body fluids. That the protein of the gland itself is not changed in quantity has recently been shown by Jackson and Gortner;<sup>3</sup> this cannot be seriously considered as a source of milk proteins. A reexamination of the quantitative relationship between the amino acids withdrawn by the mammary gland and the milk protein formed by this gland has shown that not more than from 30 to 40 per cent of the total milk protein can be accounted for by the amino acids removed from the blood if all the amino acids are changed to protein.<sup>4</sup> A more recent study has indicated other sources of the milk protein; on the basis of extensive comparisons of the analysis of arterial blood with that of mammary venous blood, Graham, Peterson and Houchin<sup>5</sup> have concluded that serum globulin is removed by the mammary glands during active secretion. Furthermore, unidentified nonprotein nitrogenous compounds as well as amino acids pass from the blood into the glands at this time. The conclusion warranted by the current evidence is that the constituents of the blood from which the milk proteins can be synthesized by the mammary glands are amino acids, serum globulin and certain nitrogenous compounds of unknown nature.

The process of elaboration of milk is accompanied by intense nitrogen metabolism of another sort, which may or may not be concerned with protein synthesis. The gland forms urea in the course of its activity, raising the concentration of this substance in the mammary venous blood over that in the arterial blood.<sup>6</sup> Nursing or milking accentuates the production of urea by the glands. Shaw and Petersen<sup>7</sup> have shown that the active glands contain arginase, whereas the quiescent glands

do not. This enzyme forms urea from the amino acid arginine and doubtless accounts for some of the urea which the gland loses to the blood. Whether the urea mechanism is a device to remove extra amino acids or is involved in the production of milk protein remains to be determined. Certain it is that recent investigation of the metabolism of nitrogen incident to the production of milk has brought us nearer to an understanding of the synthesis of proteins by the mammary gland.

## Current Comment

### SALIVARY INFLUENCE ON GALVANISM

Much has been written indicating that the electrical potential differences between dissimilar metals may produce damage to the mouth when such metals are used in dental restorations. Solomon and his co-workers<sup>1</sup> have recently reported a series of ingenious experiments to determine whether differences of potential actually exist between dental metals when saliva is the electrolyte. While the initial currents with saliva as the electrolyte are greater than currents with an artificial saliva, the final values are lower, showing that some action other than polarization is occurring, namely film formation. They concluded therefore that electric current is not normally flowing in the mouth containing dissimilar metal restorations. Although they do not maintain that electrical action resulting in damage to the soft tissues cannot exist in a mouth, the so-called protective mechanisms must be removed in order to permit current to flow. These investigators contend that there is no connection between the current readings obtained by placing a meter between metallic restorations in the mouth and damage to tissue.

### GERMICIDAL ACTION OF PROSTATIC FLUID

The demonstration by Youmans and his colleagues<sup>1</sup> of Northwestern University that prostatic fluid contains a bactericidal substance more powerful than blood serum is a belated confirmation of a generally accepted theory of genito-urinary immunity. The Northwestern University bacteriologists obtained prostatic fluid aseptically from dogs by the Farrell-Lyman technic, pilocarpine being used as the secretory stimulant. They tested its germicidal action against such micro-organisms as *Bacillus coli*, *Staphylococcus aureus*, hemolytic streptococci, *Streptococcus viridans* and the gonococcus. When *Bacillus coli*, *Staphylococcus aureus* or hemolytic streptococci were added to the undiluted prostatic fluid they found that the number of viable micro-organisms was reduced fully 95 per cent by the end of two hours. Within four to twenty-four hours all mixtures became sterile. This germicidal action was more rapid and complete than that of the blood serum of the same donors. Tests with the gonococcus showed a somewhat

slower rate of bacteriolysis, but all gonococcus mixtures became sterile by the end of twenty-four hours. The bactericidal power of canine prostatic fluid is but slightly reduced by dilution even with as much as twenty volumes of distilled water. The germicidal power, however, is reduced 50 per cent by heating the fluid to 55 C. for thirty minutes and is completely destroyed at 60 C. for thirty minutes. The bactericidal substance in prostatic fluid, therefore, is not identical with the lysozyme of tears or saliva, which resists heating to 75 C. for thirty minutes. Since the prostatic fluid will not activate hemolytic amboceptor it contains no demonstrable serum complement. Nor is the action of the germicidal factor increased by the addition of complement. Whether or not prostatic bacteriolysin is bound or inhibited in the presence of whole blood or pus has not yet been determined.

### SULFANILAMIDE AND BACTERIOSTASIS

In a recent report on the mechanism of action of sulfanilamide on bacterial infections, Osgood and Powell<sup>1</sup> found that sulfanilamide in concentrations of 1:1,000 or less did not inactivate in vitro significant amounts of the hemotoxins of the beta hemolytic streptococcus, hemolytic *Staphylococcus aureus*, *Clostridium oedematis-maligni*, *Clostridium tetani* or *Bacillus perfringens*. Neither did sulfanilamide therapy significantly affect the course of intoxication in guinea pigs injected with as little as 1 minimal lethal dose of diphtheric or tetanus toxin. The results of these experiments, therefore, fail to support, although they do not disprove, the earlier experiments with cultures of human bone marrow reported by the senior author indicating that sulfanilamide in some manner interferes with the production of the toxins responsible for the virulence of the organism and for its resistance to small amounts of bacteriocidins. Macgrath and Vollum<sup>2</sup> have recently investigated the bacteriostatic properties of three sulfanilamide derivatives using *Staphylococcus viridans* and *Staphylococcus aureus*, examined by the slide method of Wright, modified by Fleming. This technic was also used in cases of *Neisseria gonorrhoeae* and *Neisseria meningitidis*. All three derivatives apparently inhibited the growth of *Streptococcus viridans* in a dilution of 1:2,000 in the presence of defibrinated human blood but none of them were effective in the absence of leukocytes. None exhibited any bacteriostatic effects on *Staphylococcus aureus*; all three retarded the growth of *Neisseria gonorrhoeae* and *Neisseria meningitidis*. The bacteriostatic effect was dependent on the presence of leukocytes, which was in agreement with the observations previously reported by Fleming. The consensus at present is therefore that sulfanilamide and some of its derivatives exert a bacteriostatic effect in different degrees depending on the type of organism and the nature of the derivative but that the presence of leukocytes and probably some other factors are necessary for effective action.

# ORGANIZATION SECTION

## AMERICAN MEDICAL ASSOCIATION STUDY OF MEDICAL CARE

### Sullivan County, Tennessee

Sullivan County, Tenn., with a population of about 51,000, is located in the northeastern part of the state. The gainfully employed persons are about equally divided in agriculture and industry. The two industrial centers, Kingsport and Bristol, have a population of approximately 12,000 each.

The forty-six physicians in active practice in the county are located so that no person is more than 7 miles from the nearest physician. There are twenty practicing dentists, ten private duty nurses and ten public health nurses. There are two nonprofit general hospitals with a total of 111 beds. During 1937 the average bed occupancy was 41 per cent. Daily rates range from \$2.50 to \$6. In addition to two clinics operated by the hospitals there are five clinics maintained by the health departments and eight by welfare and relief agencies. Of the fifteen clinics, three provide general medical and surgical services and two are dental clinics. The rest provide limited special services but as a group they offer all types of medical and dental services.

#### *Record for One Week of Free Medical Services Furnished by Physicians*

1. Number of forms received.....	9
General practice.....	4
Surgery.....	2
Internal medicine.....	1
Eye, ear, nose and throat.....	2
2. Total number of persons who received any form of medical services in home or office.....	820
3. Total number of persons who were served without charge.....	141
4. Total number of persons referred to some other source for free medical care.....	23
5. Free surgical operations.....	13

The hospital provided 21,653 days of hospital care. Of this total, free patients received 2,716 days. In determining a patient's ability to pay, the hospital investigates his financial status and checks with the relief agency to see whether the patient is entitled to governmental aid.

Medical care for the indigents is provided by the Welfare Department, Salvation Army, Community Chest, Red Cross and Parrish Vance Foundation. These various organizations make their own investigations in determining the indigence of a person. If a person is found to be unable to pay for necessary medical care he is provided with free medical services at the various clinics. In addition to this public health nurses made 17,240 visits to patients at no charge, and the pharmacists provided 1,195 free prescriptions. The board of education provides free examinations and medical treatment for public school children.

Physicians and dentists reported that during 1937 there were thirty-two instances in which persons could not obtain medical care and the reasons given were listed as follows:

1. Lack of first class hospital.
2. Inability of patient to pay.
3. Refusal of physicians to take maternity cases in which antepartum care has not been given.
4. Refusal of patient to take advantage of services available.
5. Lack of free hospital service.

The welfare and relief agencies stated, however, that there were no cases of persons needing medical care who were not provided with the necessary services.

The amount of free medical care furnished by physicians may be estimated from the accompanying report, which is a summary of the data obtained from Form 1F.

Physicians in private practice through the health department and welfare agencies performed preventive medical services. Of the total number of children who entered school for the first time in 1937, 75 per cent were successfully vaccinated against smallpox.

In Kingsport and Bristol the larger business organizations provide industrial health services to their employees. The business men's clubs of these two cities are helpful in providing medical care, eye examinations and glasses when needed and food to needy children. In some cases these medical services are obtained for adults as well as for children.

The following comments and suggestions accompanied the county medical society summary sheet:

#### SUGGESTIONS FOR SUPPLYING MEDICAL NEEDS

##### Comments:

1. For fifteen years ample medical services have been available for all who applied.
2. Any lack of medical care in this community is due to failure of patients to avail themselves of the existent facilities.
3. A large group of diseases are nutritional rather than medical problems.
4. Many people who cannot afford adequate medical care will not go to a free clinic because of the 'stigma' attached to so doing.
5. There is a need for more adequate medical service to the indigent.

##### Suggestions:

1. Some free hospital beds for the indigent should be provided.
2. Complete care of cases should be relegated to the general practitioners. All clinic work, care of the indigent, and so on, should be done by physicians paid minimum fees for their service by relief and health agencies.
3. The most important needs in this locality are:
  - (a) Free choice of physician.
  - (b) Staff organization to improve hospital service.
  - (c) Hospitalization for very low income groups.
  - (d) A more efficient system of eliminating from charity those who are able to pay at least a small fee.
  - (e) More and better outpatient clinics.
  - (f) Organized follow-up clinics.
  - (g) Education of the public with regard to the value of medical attention early in an illness.

The county medical society makes the following conclusions and recommendations based on the experience of its members in making this study:

#### CONCLUSIONS AND RECOMMENDATIONS

It is our opinion, drawn from this study, that the medical care of the indigent is a community problem and an economic burden that has been borne too long by the physicians. The most equitable distribution of the costs of such care should be through tax support, and that cost should include anything

necessary for the care of the medically indigent person who is ill or injured, be it hospitalization, nursing or anything else that would make up an efficient medical regimen for that individual.

We advocate the free choice of physicians for the care of the medically indigent, and payment of those physicians for services rendered through the local governing unit. We have no desire to pass upon indigence because we feel that, while we have considerable information about certain families, owing to the nature of our profession, yet declaring a person medically indigent is the work of people trained for that purpose.

We disapprove of the employment of county or city physicians for the care of the poor, at least as far as it applies or is applied in Sullivan County. We find that no investigation is made of the indigent, but those who have been on the indigent roll for some time call the city or county physician to take care of their injuries or illnesses.

Owing to the past subsidization of our county health work by the Commonwealth Fund, we have a county health unit that is probably not only second to none in the state but ranks with the best of the country. It is exceptionally well housed in a building erected by the Commonwealth Fund.

The medical care of the prisoners at the county jail cannot be accomplished efficiently under the crowded, poor sanitary conditions existing in that institution. The same applies with regard to the medical care of people housed at the poor farm. The work in these two institutions is done under the supervision of county physicians who are inadequately paid for inadequate service. They have no facilities with which to do good work, and we cannot be proud of it.

The hospital service plan at Kingsport has the approval of the American Hospital Association and is working out very nicely. The hospital facilities in both Kingsport and Bristol are excellent; but this also, as far as housing and equipment are concerned, is due to subsidies by an outside agency, the Commonwealth Fund.

There is no sanatorium care provided for the patients with tuberculosis in East Tennessee. The facilities for the care of the insane are on a par with that which is happening in a large percentage of the states of the Union, in that a commitment to the state hospital automatically turns the patient over to the

sheriff, and the insane person is lodged in jail until he can be transported to an overcrowded state institution.

As already stated, we do not wish to pass upon indigence, but we wish it to be well done; and it was found during the depression of the early thirties that as a general rule counties did not have an efficient poor relief organization. We would therefore recommend that the federal government be requested by the American Medical Association to cooperate through the state government with county authorities, in subsidy funds and poor relief organization policy. Under this plan, both state and county, in order to qualify for such subsidy from the federal government, had to arrange for a businesslike efficient investigation and purchasing system in their relief work. This system, with a personnel properly selected by local county officials, was efficient. We know that the people who were doing that relief work in this county during the depression years did a good, conscientious, nonpolitical job.

The medical care of the indigent should be under the supervision of, and should be controlled solely by, physicians. The indigent person should have a free choice of physician from the list of the physicians in the county or group of counties who are willing to do this work at fees agreed on between the governing board of the county and the county medical society.

Bills for services rendered would be audited by a committee of physicians appointed by the county, and this committee should be composed of men who are willing to disagree and openly criticize any physician who attempted to impose on the system and make his relief work a "racket."

We feel definitely that there is going to be more socialization of medicine and that unless the American Medical Association and the Tennessee State Medical Association plan to meet the needs of the group who possibly cannot secure medical care and who are the group referred to by the Interdepartmental Committee in Washington as one third of the population, a system of state medicine will be crammed down our throats, and we shall have no alternative but to accept it.

We submit this plan as one that we believe will meet the need of the times and take away from the complete state medicine advocates their only definite evidence of the lack of distribution of medical care.

## GRADUATE MEDICAL EDUCATION IN MISSOURI

### Report of Recent Progress

At the last annual meeting of the Missouri State Medical Association, the Committee on Postgraduate Course recommended to the house of delegates that a correlating committee be formed of chairmen of the various state society committees concerned with professional and lay education.<sup>1</sup> October 13 the Postgraduate Correlating Committee was effected, with Dr. C. H. Neilson, who has been active in arranging postgraduate courses for several years, as chairman of the newly formed correlating committee and representatives from the committees on cancer, conservation of eyesight, fractures, health and public instruction, maternal welfare, medical economics, mental health, publication, physical therapy and the control of syphilis. Dr. John W. Williams, assistant health commissioner, also attended this meeting.

In the future the educational activities of these committees of the state association will be reviewed by the correlating committee, thus avoiding duplication of effort and insuring a well planned, comprehensive and continuous program of professional and lay instruction. Particular stress is to be given to the recording and publication of attendance at both scientific and lay meetings.

1. Association's Postgraduate and Health Education Activities Correlated, *J. Missouri M. A.* 35:454 (Nov.) 1938.

The newly formed correlating committee will strive to demonstrate to the public that individual practicing physicians are being thoroughly instructed and informed on the recent advances in medical science and practice under the present system of individual care. The plan of professional and lay education on preventive medicine of the Indiana State Medical Association, approved by the House of Delegates of the American Medical Association at the San Francisco session, forms the principles on which the Missouri association's postgraduate correlating committee will function. These are:

1. The selection of a specific disease or health problem of major importance for discussion in the state association's journal and in each county medical society. For each successive month, beginning in December, the following subjects have been chosen: pneumonia, highway accidents, syphilis, maternal and infant care and diphtheria. It is suggested that each component society select speakers from its own membership, whenever possible, to discuss current topics. Articles published in the journal should be of considerable assistance. Smaller county societies might arrange to meet jointly when circumstances permit.

2. Continued cooperation with the state board of health in the statewide program of lectures in obstetrics and pediatrics is strongly urged. Likewise, in the discussions of syphilis, the profession should be completely informed of the board's plan for the control and treatment of this disease.

3. The correlating committee does not propose to interfere with the activities of individual committees. As in the past,

the office of the state association will continue to be the clearing house for all committee activity. The number of physicians attending scientific sessions and the lay interest in health programs is to be reported routinely by the secretary of each component society to state association's office.

4. It has become a policy for the speaker designated for professional audiences to address lay groups as well when so requested by the local society.

5. Publicity on preventive health educational activities will be directed by the postgraduate committee in cooperation with the state association's office and component societies. Members of the committee on postgraduate course "believe that through such correlated activity we can successfully demonstrate to the public that individual practitioners of medicine are being thoroughly instructed and informed on the latest methods of medical progress. . . ."

## OFFICIAL NOTES

### WITNESSES BEFORE THE SPECIAL GRAND JURY IN WASHINGTON

The following additional witnesses are reported to have appeared before the Special Grand Jury in Washington, D. C.: Dr. John E. Rueth and Dr. Adam L. Curtin, both of Milwaukee.

### RADIO BROADCASTS

The fourth series of programs broadcast in dramatic form portraying fictitious but typical incidents of significance in relation to health by the American Medical Association and the National Broadcasting Company, entitled "Your Health," began Wednesday October 19 and will run consecutively for thirty-six weeks. The program is broadcast each Wednesday over the blue network of the National Broadcasting Company at 2 p. m. eastern standard time (1 p. m. central standard time, 12 noon mountain time, 11 a. m. Pacific time).<sup>1</sup>

These programs are broadcast on what is known in radio as a sustaining basis; that is, the time is furnished gratis by the radio network and local stations and no revenue is derived

1. Owing to program conflicts, there will be no Chicago broadcast of the network program. Instead, a recording of the program will be broadcast over station WENR at 8 p. m. each Wednesday. This recording will be an identical rebroadcast of the network program broadcast earlier the same day.

from the programs. Therefore, local stations may or may not take the program, at their discretion, except those stations which are owned and operated by the National Broadcasting Company.

The next three programs to be broadcast, together with their dates and their topics, are as follows:

December 21. Hidden Treasures in Foods.  
December 28. Good Milk, Good for You.  
January 4. Fool's Gold.

### SPECIAL BROADCAST ON INFANTILE PARALYSIS

The American Medical Association and the National Broadcasting Company, in cooperation with the National Foundation for Infantile Paralysis and the Committee for the Celebration of the President's Birthday, will broadcast a special program on infantile paralysis over the red network of the National Broadcasting Company December 19 at 11:30 p. m. to midnight, eastern standard time (10:30 central standard time, 9:30 mountain time and 8:30 Pacific time).

This will be a dramatized program, with music, along the same general lines as the regularly weekly programs in the Your Health series. The program will be conducted by Dr. W. W. Bauer and the principal speaker will be Dr. Morris Fishbein.

## WOMAN'S AUXILIARY

### Georgia

Dr. Grady N. Coker, president of the Medical Association of Georgia, spoke on "Our Problems" at a recent meeting of the auxiliary to the First District Medical Society. Dr. W. H. Myers, president-elect, spoke on "What Is Happening in the Practice of Medicine."

The auxiliary to the Third District Medical Society held a joint meeting with the society in Eastman recently. Speakers and their subjects were as follows: Mrs. Warren A. Coleman, president of the auxiliary to the Medical Association of Georgia, "Auxiliary Activities for 1938-1939"; Mrs. Eustance Allen, president-elect, "Organization"; Mrs. John Persall, "The Jane Todd Crawford Memorial," and Mrs. R. L. Cater, "Research in the Romance of Medicine."

### Iowa

The auxiliary to the Dallas-Guthrie Medical Society met at Panora October 20. Mrs. Dean W. Harman, president of the Iowa Auxiliary, gave the four auxiliary objectives for the year: 1. Extend aim of medical society to all organizations interested in health. 2. Assist in entertainment work at state meetings. 3. Promote friendship among families of physicians. 4. Continue to cooperate with medical societies in all tasks for which they ask our help.

### New Jersey

The auxiliary to the Atlantic County Medical Society met October 4 at the Ambassador Hotel, Atlantic City. Dr. Hilton S. Read was speaker. Mrs. Andrew Smith, president, announced the essay contest sponsored by the auxiliary for children of the seventh and eighth grades of the public schools of Atlantic County.

The auxiliary to the Bergen County Medical Society met at Teaneck October 11. At the request of the society, three needy physicians will be assisted from the philanthropic fund of the auxiliary.

The auxiliary to the Hudson County Medical Society met in Jersey City October 3. Mr. David Armstrong, professor of English in the Emerson High School, Union City, reviewed the Biography of Madame Curie, written by her daughter.

The auxiliary to the Middlesex County Medical Society met at Perth Amboy October 27. Mrs. Don Epler, president of the state auxiliary, was guest of honor. Dr. Rita Finkler of Newark, director of the biologic laboratory at the endocrine clinic, Beth Israel Hospital, Newark, spoke on "Recent Advances in Endocrinology."

Dr. Sigurd Johnsen of Passaic spoke on "Socialized Medicine" at the meeting of the auxiliary to the Passaic County Medical Society October 10.

### Oklahoma

The auxiliary to the Woodward County Medical Society, comprising the five counties of Beaver, Harper, Ellis, Dewey and Woodward, hold joint meetings alternate months. October 15, Dr. Louis H. Ritzhaupt spoke on "Socialized Medicine." The project for the year is to organize a speakers' bureau and to furnish programs on public health for lay groups.

The auxiliary to the Pontotoc County Medical Society met in Ada October 19. Mrs. C. F. Needham gave a talk on "Public Relations." The auxiliary is cooperating with the American Association of University Women in federal nursery work and during the past month supplied cod liver oil, food-stuffs and toilet articles for thirty needy children.

The auxiliary to the Tulsa County Medical Society held a tea in Tulsa October 4 with ninety-two members present. Copies of "On the Witness Stand," a booklet on socialized medicine, was distributed.

### Tennessee

The Woman's Auxiliary to the Nashville Academy of Medicine and the Davidson County Medical Society gave a dinner October 24 in honor of Dr. Harrison H. Shoulders, Nashville, Speaker of the House of Delegates of the American Medical Association, and Mrs. Shoulders.

### Wisconsin

The auxiliary to the Dane County Medical Society met in Madison October 12. Mr. J. G. Crownhart, secretary of the Wisconsin Medical Society, spoke on "Looking at Sickness Care in Europe." Mr. Crownhart was speaker also at the meeting of the Milwaukee County auxiliary October 14 on the subject "Current Medical Problems."

The auxiliary to the Sheboygan County Medical Society assisted the society and the Crippled Children's Division of the Department of Public Instruction at the orthopedic clinic held in Sheboygan September 26.

## MEDICAL ECONOMIC ABSTRACTS

### DIPHTHERIA PREVENTION IN ENGLAND

A vivid comparison of the preventive measures taken against diphtheria and the results of such measures in the United States and Great Britain is found in the following extract from the Annual Report of the Chief Medical Officer of the Ministry of Health for the year 1937 "On the State of the Public Health," London, 1938, pages 53-55:

In 1937, 61,339 cases of diphtheria were notified as compared with 57,795 in 1936 and 65,084 in 1935. The fatal cases numbered 2,963, giving the fatality rate of 4.8 per cent as compared with 5.3 per cent and 5.4 per cent in 1936 and 1935 respectively. In diphtheria we appear to have reached a position of stability so far as incidence is concerned within the limits of what may be regarded as normal fluctuation, and it is doubtful whether any marked diminution of incidence can be expected by procedure along the old lines of "notification, removal and disinfection."

Approximately 90 per cent of cases of diphtheria occur under the age of 15 years. By that time the great majority of individuals have become immunized by the subclinical infection. This is a measure of the amount of natural subinfection which is constantly taking place. The acquisition of immunity by natural means postulates a diphtheritic environment. It is a lengthy process and is obtained at the expense of a number of clinical cases, and possibly of deaths, whereas artificial immunity if carefully conducted by experts is without these risks and can be acquired in as many months as the natural process takes years. A clear indication would appear to be to induce a wider adoption of artificial immunization, such as has been practiced in certain cities of the United States of America and in Canada with extraordinary success.

#### RESULTS OF IMMUNIZATION IN NORTH AMERICA

In New York immunization against diphtheria has been a practice for about twenty years. An intensive campaign began in 1929 and by the middle of 1935 more than 1,110,000 children under the age of 15 years were immunized in addition to those protected in previous years.

Before 1929 comparatively little attention has been paid to children of preschool age on whom, as previously pointed out,<sup>1</sup> the maximum incidence and fatality falls, but in 1929 in New York special attention was paid to the children, and the total number of immunized persons rose from 212,000 in 1929 to 1,114,325 in 1935. Of this last number 650,000 were under the age of 6 years and it is estimated that between 65 and 70 per cent of them had been protected. There resulted a reduction in diphtheria incidence from 8,548 cases in 1929 to 1,143 in 1936. That is to say, the incidence in the latter year was about one-eighth what it had been in the former. During the same period the deaths diminished from 463 to thirty-five. The later figures represent a reduction in the diphtheria death rate in the age period 1 to 15 from 27.4 to 2.1 per hundred thousand. The corresponding figures for England and Wales are 32.8 and 31.8 respectively.

In Montreal, among a population of 657,000 in 1928 when immunization was commenced, there were 1,632 cases and 157 deaths from diphtheria. Both incidence and mortality fell *pari passu* with immunization until in 1935 there were 183 cases

and twenty-one deaths, approximately one tenth of the figures recorded in 1927. As in New York, a particular effort to secure the protection of young children was made and it was calculated that by the end of 1935 over 50 per cent of the child population under the age of 12 was immunized. Among other smaller cities of Canada showing an almost similar record are Toronto (650,000), Hamilton (150,000), where there has been no case of diphtheria notified since 1933 and no death since 1930, Brantford (31,382) and St. Catharines, Ont. (27,000). Of Brantford it is said that no child has suffered from diphtheria there since 1930, and from that date no resident of St. Catharines has died from diphtheria.<sup>2</sup>

These results have been achieved only by intensive propaganda on the part of local authorities, assisted in some degree by insurance interests, and it is, of course, necessary to ensure that the immune population thus obtained is not unduly diluted with nonimmunes in the persons of recently born infants, for, as Dr. Graham Forbes<sup>3</sup> recently observed, the further success of immunization must be dependent on the respective campaigns being continuous and unremitting in order to keep the protection rate at least equal to one-half the number of births each year.

It is now six years since the minister issued his memorandum on "The Production of Artificial Immunity against Diphtheria" and drew the attention of local authorities to the advantages of this process, at the same time expressing the opinion that the public should be made aware of them, and, where practicable, parents and guardians of children over 1 year of age should be offered the necessary facilities for protection. A survey of the annual reports for 1936 of medical officers of health, the last complete available information, shows that local authorities generally are well acquainted with the memorandum and continuous if slow progress is being made, particularly in some of the larger provincial cities, although none of them have yet succeeded in immunizing the 50 to 60 per cent of the child population which is necessary before the incidence of the disease is affected. Chester, with an estimated number of 45 per cent, is probably the best immunized town in the country; then follow in close order Birmingham, Walsall, Worcester, Leeds, Manchester and Chatham, all of which are in the neighborhood of from 35 to 40 per cent. Other towns with more than 30 per cent are Wood Green, Wakefield, Salford, Blackburn, Swindon, Cardiff and Acton. London (all the metropolitan boroughs combined) appears very low in the list, with an estimated number of 5.3 per cent of her child population immunized.

It may be said in conclusion that artificial immunization against diphtheria as done in the United States and Canada has been attended by extraordinarily good results. This work has to be persisted in over a long period of time before the necessary number of immunes are obtained to affect the incidence of the disease. It is unfortunate that the exact technique, preparation of vaccine and method of administration are still matters of medical controversy. It is probable that the lack of a general standard has militated against the more general adoption of antidiphtheritic immunization in this country. It is a form of preventive treatment which in the future may succeed in eradicating diphtheria from our midst and thus save countless lives. It is desirable that medical practitioners should

2. Fitzgerald, J. G.; Fraser, D. T.; McKinnon, N. E., and Ross, Mary A.: *Lancet* 1: 391 (Feb. 12) 1938.  
3. Forbes, J. Graham: *Brit. M. J.* 2: 1209 (Dec. 18) 1937.

1. Annual Report of Chief Medical Officer of Ministry of Health for 1934, p. 26.

acquaint themselves with the minister's memorandum and, if possible, gain practical experience at a clinic where immunization is done, in order that they may be familiar with the method when called on to apply it. The medical officer of health of the county or county borough concerned is usually able to make the necessary arrangements for medical practitioners to acquire experience in the technic employed in Schick testing and immunization, and applications should be made to him.

## INFANT MORTALITY IN GERMANY

When so much is being said about comparative infant mortality statistics, it is worth while to look at some of the facts. Germany has had sickness insurance longer than any other nation in the world. In the *Deutsches Aerzteblatt* (68:681 [Oct. 1] 1938) Hans Klepp reports on "The Struggle Against Infant Mortality" and gives a table showing the course of infant mortality during the present century, from which the following figures are taken:

Death Rate per Thousand Live Births During the First Year

Year	Male	Female	Both
1901.....	223	190	207
1905.....	222	188	205
1910.....	176	147	162
1913.....	164	137	151
1914.....	177	149	164
1918.....	172	143	158
1919.....	158	131	145
1923.....	144	118	131
1928.....	99	79	89
1929.....	107	86	97
1932.....	87	71	79
1933.....	85	68	77
1935.....	77	60	69

The Bureau of the Census, Department of Commerce, has also issued a summary of the changes in infant mortality in the registration area since 1915 (Vital Statistics—Special Reports 5:47 [March 1] 1938). Every state that is in any way comparable as to climate and racial uniformity with Germany shows a lower infant mortality rate. Of eleven northern states that have been in the registration area since 1920, the range of the infant death rate per thousand in 1935 is between 41.2 for Oregon and 53.9 for New Hampshire.

## PWA HOSPITAL CONSTRUCTION

According to a report on "Allotments for Hospital Construction" by the Federal Emergency Administration of Public Works, Projects Division, Research Section, Dec. 2, 1936, and supplemental report as of Jan. 15, 1938, the total estimated cost of constructing and equipping 1,161 hospital buildings was \$194,567,038. Nine hundred and twenty-two of these buildings had reached a point where it was possible to determine the number of additional beds provided, which amounted to 51,207.

## DISCOVERING THE OBVIOUS

The United States Department of Agriculture reports on part of "a nation-wide study of how much money the American family makes and how it is spent." This proves once more that low income families consult dentists less frequently than doctors and that visits to the oculist usually are omitted entirely. It demonstrates again that persons with an annual income of less than \$500 spend less for medical care than higher income families. It was also discovered that "a majority of families with very low incomes did not have periodic physical examinations by a doctor." The report does not state whether those with higher incomes had such periodic physical examinations. What this report and all others like it fail to tell is that almost all that is being done about this condition is due to the action of organized medicine and individual physicians, assisted by relief appropriations in some cases. Neither, of course, are any comparisons made to indicate whether the medical care received by members of the same income levels in other countries is as good as or better than the care received in the United States.

## INCOMES OF PHYSICIANS

A survey of the income of some types of professional workers by the United States Bureau of Foreign and Domestic Commerce is summarized in the *Monthly Labor Review* (47:1114 [Nov.] 1938).

As table 1 shows, the number of practitioners in the sample was too small to make the estimates given reliable as measures

TABLE 1.—Net Income of Independent Professional Practitioners, 1929-1936

Profession	Average Net Income							
	1929	1930	1931	1932	1933	1934	1935	1936
Medical

Over 52 years.....	2	0.2	678	6	0.6	1,245

of the income of all physicians. Nevertheless, the agreement of the figures given with other investigations lends some measure of confidence regarding the accuracy of the results.

An effort is also made to determine the income by years of experience. Here again the number in some years is so small as to indicate a large "probable error," which should be kept in mind in any use that may be made of these statistics.

## Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

### ARIZONA

**Annual Registration Due January 1.**—Every person practicing medicine, surgery or osteopathy in Arizona is required by law to pay annually on or before January 1, to the board of medical examiners, a renewal license fee of \$3. Any licentiate who does not renew his license as required is to be penalized \$1 for each day that he practices without a renewal license, not to exceed \$50. The board of medical examiners is to revoke the license of any licentiate who fails to renew his license for three successive years.

### ARKANSAS

**Annual Reregistration Due January 1.**—Every licentiate of the Arkansas Eclectic Medical Examining Board must register annually with the secretary of the board between January 1 and the last day in February and pay a fee, if a resident of Arkansas, of \$2, and, if a nonresident, of \$4. The failure of a licentiate to pay the required fee by March 1 automatically suspends his right to practice while delinquent. If he fails for three successive years to pay the required fee his license is to be canceled, and thereafter he will be reinstated only on such a showing to the board of moral character and professional qualifications as would entitle the applicant to the issuance of an original license and the payment of the same fee as is required for the issuance of an original license.

### CALIFORNIA

**Annual Registration Due January 1.**—Every practitioner of medicine and surgery holding a license to practice in California is required by law to register annually, on or before January 1, with the secretary-treasurer of the board of medical examiners and at that time to pay a fee of \$2. Failure to pay the required fee within sixty days after January 1 works a revocation of a license and thereafter a license may be reissued only after application and the payment of a \$10 penalty.

**Four Persons Indicted for Treating Alcoholism.**—Four persons were indicted by the grand jury November 19 on charges by the state board of medical examiners that a South American arrow poison had been used in the treatment of alcoholic addicts, according to the newspapers. Under indictment were Thomas F. H. Huston, proprietor of the "Samaritan Treatment," an establishment offering to cure alcoholism, and his assistant, John A. Stevens, neither of whom has a medical degree; and two nurses, Ruth Nielsen and Juanita Butcher. It was stated that more than 200 complaints have been received by the state board against the treatment. The newspapers reported that two investigators for the board found that curare was used in the treatment.

**Positions Open for Physicians.**—The state personnel board announces several positions open for physicians, the examinations to be held January 5. There are vacancies for physician and internist, junior physician, physician (eye, ear, nose and throat) and physician and surgeon. Applications by nonresidents must be filed by December 26. Examinations will be held in San Francisco, Los Angeles, San Diego, Sacramento, Fresno, New York, Chicago, St. Paul, Madison, Wis., Washington, D. C., Denver, Portland, Ore., Seattle, Dallas, Texas, Columbus, Lansing, Mich., Jacksonville, Fla., Baltimore, Boston, and Phoenix, Ariz., and such other cities outside the state of California as the number and location of candidates may warrant. Information may be obtained from the state personnel board, 1025 P Street, Sacramento.

### CONNECTICUT

**Personal.**—Dr. Julius Lane Wilson, assistant clinical professor of medicine, Yale University School of Medicine, New Haven, has been appointed associate professor of medicine at Tulane University of Louisiana School of Medicine, New Orleans.—Dr. Russell V. Fuldner, chief, division of crippled children, state department of health, Hartford, has resigned to accept a residency in orthopedic surgery at Massachusetts General Hospital, Boston.

**Annual Registration Due During January.**—Every practitioner of medicine and surgery holding a license to practice in Connecticut is required by law to register during January with the state department of health and at that time to pay a fee of \$2. Licentiatees who have retired from active practice or who live out of the state must register annually but need not pay a fee. A practitioner failing to register is liable to a fine of not more than \$5.

**Exhibition of Rare Medical Volumes.**—Yale University School of Medicine, New Haven, recently sponsored an exhibition of books commemorating the two hundredth anniversary of the death of Hermann Boerhaave, professor of botany, chemistry and clinical medicine at the University of Leyden. Boerhaave was born in 1668 and died in 1738. Lent by Dr. John F. Fulton, Sterling professor of physiology at Yale, the books included a first edition of Boerhaave's "Institutiones Medicae," published in 1708, which for the first time established physiology as an academic discipline in the medical curriculum, according to *Science*, and was written to give his students a background of knowledge of normal function; in the work he introduces the term "physiology" in its modern connotation.

### FLORIDA

**Annual Registration Due January 1.**—Every practitioner of medicine and surgery holding a license to practice in Florida is required by law to register annually on or before January 1 with the secretary of the state board of health and at that time to pay a fee of \$1. A licentiate failing to register annually is liable to a fine of not more than \$50.

**Personal.**—Dr. Terry Bird, Tavares, has been appointed in charge of the newly created Lake County health unit.—Dr. James Maxey Dell Sr., superintendent of the Florida Farm Colony, was named mayor-commissioner of Gainesville recently, succeeding R. B. Livingston.—Dr. Lauren M. Sompayrac, Jacksonville, was recently awarded the Robert L. Schermer Cup by the local junior chamber of commerce in recognition of his "meritorious leadership" during the past six months. Dr. Sompayrac graduated from the University of Pennsylvania School of Medicine, Philadelphia, in 1935.

### ILLINOIS

**Society News.**—Dr. Norbert C. Barwasser, Moline, discussed the management of common skin diseases before the Whiteside County Medical Society, Sterling, November 21.—The Peoria City Medical Society was addressed November 1 by Lewis Gerber, Ph.D., on "Recent Advances in Clinical Chemistry" and Dr. Hugh E. Cooper on "Fractures of the Shaft of the Femur."—Dr. Edmund F. Foley, Chicago, discussed "Jaundice: Its Clinical Significance" before the Adams County Medical Society in Quincy November 14.—Dr. Fred W. Bailey, St. Louis, discussed "Nonpenetrating Intra-Abdominal Injuries" before the Madison County Medical Society in Alton November 4.

### Chicago

**Lectures on Psychoanalysis.**—A group of introductory lectures on psychoanalysis began at the University of Illinois College of Medicine November 30 under the auspices of the Institute for Psychoanalysis. Dr. Franz Alexander, director of the institute, is making a systematic presentation of medical psychoanalysis. Sixteen weekly lectures make up the course, which carries a fee of \$10.

**Society News.**—The Chicago Laryngological and Otological Society was addressed November 7 by Drs. Ellison L. Ross on "Experiences with a Vital Stain in Otolaryngeal Tissues"; Frank E. Simpson, "Intrinsic Carcinoma of the Larynx—A New Instrument Modeled After the Jackson Bronchoscope for the Intralaryngeal Application of Radon," and Hans Brunner, "Inflammatory Diseases of Meninges and Brain of Pharyngeal Origin."—Dr. Frederick A. Collier, Ann Arbor, Mich., discussed "Hypochloremia Associated with Surgical Diseases" before the Chicago Surgical Society November 4; Drs. Loyal Davis and John Martin, "Surgical Aspects of Paratrigebral Lesions," and Geza DeTakats, "Observations of Congenital Megacolon."

### KENTUCKY

**Date of Dr. J. N. McCormack's Death.**—In the news item concerning the new building of the Kentucky State Board of Health and the Kentucky State Medical Association recently dedicated as a memorial to Dr. Joseph N. McCormack, published in THE JOURNAL December 10, page 2219, the date of Dr. McCormack's death should have been May 4, 1922, instead of Aug. 4, 1922.

## LOUISIANA

**Annual Renewal Due January 1.**—Every practitioner of medicine and surgery holding a certificate to practice in Louisiana is required by law to have his certificate renewed annually on or before January 1 by the secretary-treasurer of the state board of medical examiners and at that time to pay a fee of \$2. The board may by unanimous vote revoke any certificate not renewed.

**Society News.**—At a meeting of the Orleans Parish Medical Society in New Orleans November 14 Drs. Richard S. Crichtow spoke on "Treatment of Headache with Theelin"; Upton W. Giles, "The Historical Development and Modern Application of Artificial Fever," and George Gordon McHardy III, "Peritoneoscopy."—Dr. Edward Garland Walls was recently elected president of the New Orleans Eye, Ear, Nose and Throat Club and Dr. William B. Clark secretary-treasurer.

## MASSACHUSETTS

**Infectious Encephalitis Made a Reportable Disease.**—At a meeting of the public health council in Boston October 11 it was voted to substitute the term "infectious encephalitis" for "encephalitis lethargica" on the list of reportable diseases in Massachusetts. The change was made because of the belief that the term "encephalitis lethargica" is not broad enough to include all cases of encephalitis that are of possible danger to public health. The new terminology will exclude encephalitis caused by chemicals and degenerative changes. On the other hand, "infectious encephalitis" should include cases of encephalitis which appear to result from an apparent communicable disease or vaccination.

**Dr. Christian to Retire from Brigham Hospital.**—Dr. Henry A. Christian, Hersey professor of the theory and practice of physic, Harvard Medical School, Boston, will retire next September as physician-in-chief of Peter Bent Brigham Hospital, a position he has held since the hospital was completed in 1912. A portrait of Dr. Christian was presented to the hospital corporation October 13 at a gathering of 350 friends and pupils. Dr. Christian received his medical degree at Johns Hopkins University School of Medicine, Baltimore, in 1900. He was pathologist at the Boston City Hospital from 1900 to 1905 and at the Children's Hospital, Boston, 1903 to 1905. During the latter period he taught pathology at the Harvard Medical School, changing in 1905 to the theory and practice of physic, becoming Hersey professor in this subject in 1908. He was dean of the medical school from 1908 to 1912 and physician-in-chief to Carney Hospital from 1907 to 1912. He was secretary of the Section on Pathology and Physiology of the American Medical Association from 1903 to 1905, chairman of the section from 1905 to 1907 and of the Section on Practice of Medicine, 1916-1917. He was resident chairman of the division of medical sciences of the National Research Council, 1919-1920; president of the American Society for Clinical Investigation in 1919 and the Association of American Physicians in 1935. He is editor for the Oxford University Press of Oxford Medicine and Oxford Monographs and has contributed extensively to medical literature. On his sixtieth birthday in 1936, Dr. Christian was presented with a volume of medical papers dedicated to him by his former students and colleagues.

## MINNESOTA

**Annual Registration Due During January.**—Every practitioner of medicine and surgery holding a license to practice in Minnesota is required by law to register annually during January with the secretary of the board of medical examiners and at that time to pay a fee of \$2. A licentiate who practices without renewing his license is guilty of a misdemeanor and is liable to prosecution.

## MISSOURI

**Pilgrimage to Beaumont's Grave.**—The St. Louis Medical Society conducted its annual birthday pilgrimage to the grave of William Beaumont November 21. Rev. Harry B. Crimmins, S.J., president of St. Louis University, where Beaumont was the first professor of surgery, was the speaker.

**Society News.**—At a meeting of the Boone County Medical Society in Columbia October 4 the speakers included Dr. William J. Stewart, Columbia, on "The Smith-Petersen Nail in Treatment of Fractures of the Femur."—At a meeting of the Buchanan County Medical Society in St. Joseph November 2 Dr. Thomas L. Howden discussed "Common Types of Neuroses."—The Southeast Missouri Medical

Society held its sixty-second annual meeting at Poplar Bluff October 11-12. Dr. George W. Vinyard, Jackson, the only living charter member of the society, was present. Dr. Bernard J. Macauley, Poplar Bluff, was chosen president and Cape Girardeau was selected as the place of the next annual meeting in October.

## NEW JERSEY

**Scarlet Fever Isolation Period Reduced.**—The state department of health recently amended the state sanitary code to reduce the minimum period of isolation of cases of scarlet fever. The amendment, which went into effect October 1, changes the quarantine from thirty to twenty-one days.

**Second Councilor District Meeting.**—At a meeting of the Second Councilor District of the Medical Society of New Jersey in Jersey City December 15 the speakers were Drs. Morris Fishbein, Chicago, Editor of THE JOURNAL, on "American Medicine and the National Health Program"; William J. Carrington, Atlantic City, president of the state society, "Medicine in the News," and Hilton S. Read, Atlantic City, "Voluntary Medical Costs Insurance."

**Annual Health Meeting.**—The sixty-fourth annual meeting of the New Jersey Health and Sanitary Association was held at Asbury Park November 18-19. There were sessions on cancer, mental hygiene and social hygiene, motion picture showings, a microscopic exhibit of common parasites in New Jersey and an exhibit of publicity material. Among the speakers were Drs. William G. Herrman, Asbury Park, chairman of the cancer control committee of the Medical Society of New Jersey, on "The Cancer Situation in New Jersey"; Clarence C. Little, Sc.D., Bar Harbor, Maine, managing director, American Society for the Control of Cancer, "The Public and Cancer Control"; Haven Emerson, New York, "Signs of the Times in Public Health," and Mr. Homer Calver, director of health exhibits, New York World's Fair, "Health Exhibits, World's Fair and Otherwise."

## NEW YORK

**Annual Graduate Lectures.**—The eleventh annual series of graduate lectures sponsored by the Medical Society of the State of New York in Rochester was presented during October. The following addresses were given:

Dr. Samuel J. Kopetzky, New York, October 3, Recent Developments in the Treatment of Paranasal Sinusitis and Mastoiditis, Including the Use of Roentgenology and Chemotherapy.

Dr. Foster Kennedy, New York, The Organic Background of Mind.

Dr. Samuel W. Clausen, Rochester, Latest Developments in Vitamins.

Dr. Henry H. Ritter, New York, Treatment of Burns and Hand Infections.

Dr. Henry Rawle Geyelin, New York, Diabetic Coma.

**Annual Registration Due January 1.**—Every practitioner of medicine and surgery in New York is required by law to apply annually, on or before January 1, to the secretary of the board of medical examiners for a certificate of registration, on application forms furnished by him, and to pay at that time a fee of \$2. The law authorizes the secretary of the board to permit secretaries of duly incorporated medical societies to act as his representatives, to receive and transmit to him such applications and fees. Practitioners are liable to severe penalties for failing to register and for continuing in practice thereafter.

### New York City

**Another Orchestra.**—The Doctors' Musical Society of Brooklyn was recently organized and an orchestra is in process of formation. Dr. Harry Tevel Zankel, 614 Eastern Parkway, Brooklyn, is secretary.

**Brickner Lecture.**—The eighth Walter M. Brickner Lecture was given at the Hospital for Joint Diseases November 17 by Dr. Charles A. Elsberg. His subject was the orthopedic and neurologic significance of back pain.

**Bronx Society to Honor Dr. Van Etten.**—The Bronx County Medical Society will celebrate its twenty-fifth anniversary Jan. 7, 1939, with a dinner dance at which Dr. Nathan B. Van Etten will be the guest of honor. Dr. Van Etten, for several years medical director of Morrisania Hospital, was the first president of the Bronx County society. For three years Dr. Van Etten was Speaker of the House of Delegates of the American Medical Association, having retired at the San Francisco session in June. In 1925 he was president of the Medical Society of the State of New York.

**Society News.**—Drs. John G. Kidd and Fred W. Stewart, New York, addressed the New York Pathological Society November 18 on "Immunologic Studies with Virus-Induced and Transplantable Growths of Rabbits" and "Use

of the Aspiration Biopsy in Diagnosis of Tumors" respectively. Dr. Richard E. Shope of the Rockefeller Institute for Medical Research, Princeton, N. J., delivered the Middleton Goldsmith Lecture December 7 on "Complex Infections."—At a meeting of the New York Diabetic Association with the section of medicine of the New York Academy of Medicine December 20 the speakers will be Drs. Herman Lande, on "Present Status of Protamine Zinc Insulin Therapy"; Edward Tolstoi, "Protamine Zinc Insulin: A Metabolic Study of Two Severe Cases of Diabetes with Comments on Criteria for Treatment," and Henry Rawle Geyelin, "Management of Diabetic Acidosis and Its Accompanying Medical Shock."—Dr. William Osler Abbott, Philadelphia, will address the New York Roentgen Society December 19 on "The Role of Small Intestinal Intubation in the Treatment and Diagnosis of Intestinal Obstruction."

### NORTH DAKOTA

**Annual Registration Due January 1.**—Every practitioner of medicine and surgery holding a license to practice in North Dakota is required by law to register annually on or before January 1, with the secretary-treasurer of the board of medical examiners and at that time to pay a fee of \$5 if a resident of North Dakota or \$2 if a nonresident. A practitioner may not lawfully practice if he has not registered. If he does so his license may be revoked and can be reinstated on the payment of unpaid fees and \$0.50 for each month of default.

### OHIO

**Western Reserve Selected for Cancer Training Center.**—The National Cancer Institute has chosen Western Reserve University School of Medicine as one of the centers for training of physicians in the diagnosis and treatment of cancer. Appointments are filled at present, but, as vacancies may arise, those interested should apply promptly to the Surgeon General, U. S. Public Health Service, Washington, D. C. Appointments are for two years, with eight months each of pathology, radiology and surgery. Applicants must have had at least three years of hospital training, one of which may have been a rotating internship; at least two years must have been in surgical experience. Not more than one trainee can be accepted at present, but the number may later be increased to three, according to the announcement. Trainees will be paid by the National Cancer Institute on a per diem basis, out of which they will be expected to pay all the necessary expenses, including tuition, if any is charged by the institution which accepts them for training. Stipends for training will range from a per diem allowance of from \$5 to \$10, depending on training, experience and other considerations. Further information and application blanks may be obtained on written request to the Surgeon General at Washington or from Dr. John H. Lazzari, Secretary of the Cancer Training at Western Reserve University, Republic Building, Cleveland, Ohio.

### OREGON

**Society News.**—Dr. Herbert Van H. Thatcher, Portland, addressed the Central Willamette Medical Society, Newport, recently on "Injuries of the Hand."—Dr. Warren G. Bishop addressed the Jackson County Medical Society, Medford, recently on common colds.—Dr. Arthur J. McLean addressed the Multnomah County Medical Society, Portland, October 19 on "The Adequate Neurological Examination," and Dr. Homer P. Rush gave a demonstration of electrocardiography. The speaker October 5 was Dr. Robert W. Langley, Los Angeles, on "Heart Sounds: A Clinical Experiment in Sound Photography." The society held its first hobby show September 24 with sixty physicians as exhibitors; more than 1,000 persons attended.

### PENNSYLVANIA

**Annual Registration Due January 1.**—Every practitioner of medicine and surgery holding a license to practice in Pennsylvania is required by law to register annually on or before January 1 with the board of medical education and licensure in the department of public instruction and to pay a fee of \$1 or such fee as may be fixed by the department of public instruction. A practitioner who fails to register and who continues to practice is liable to a fine of from \$10 to \$100.

**Society News.**—Dr. Albert D. Ruedemann, Cleveland, addressed the Cambria County Medical Society, Johnstown, November 10, on "A Clinical Survey of 100 Cases of Headache."—Drs. Arthur Carlton Ernestine and Robert S. Dinsmore, Cleveland, addressed the Lycoming County Medical

Society, Williamsport, at its annual clinic meeting November 11 on "Use of Drugs in Heart Disease" and "Problems in Thyroid Surgery" respectively.—Drs. Thomas B. Herron, Monessen, and Albert S. Sickman, Lock No. Four, addressed the Washington County Medical Society at Lock No. Four November 9 on "The Ruptured Appendix" and "Immediate Operation of Compound Fractures" respectively.—Dr. Edward S. Dillon, Philadelphia, addressed the Delaware County Medical Society, Chester, November 10 on "Diabetic Coma."—Dr. Charles F. Geschickter, Baltimore, addressed the Northampton County Medical Society November 17 on "Neoplasms of the Mammary Gland."

### RHODE ISLAND

**Subject for Fiske Fund Essay.**—The trustees of the Fiske Fund, administered by the Rhode Island Medical Society, have chosen the following subject for the prize essay of 1939: "Cesarean Section—Indications and Contraindications for the Various Types of Operations." Competitors must forward to the secretary, Dr. Wilfred Pickles, 184 Waterman Street, Providence, copies of their dissertations before May 1, 1939. Each must be identified by a motto and accompanied by an envelop bearing the same motto on the outside and the name and address of the sender within.

### SOUTH CAROLINA

**Dr. Jervey Honored.**—The Greenville County Medical Society held a dinner in honor of Dr. James W. Jervey, Greenville, then president of the Southern Medical Association, November 7 in Greenville. The speakers were Drs. William Weston, Columbia; Robert Wilson, Charleston; Frank H. McLeod and William S. Fewell, Greenville. At the society's meeting Drs. Edwin A. Merritt, Washington, D. C., and Kenneth M. Lynch, Charleston, spoke on "Carcinoma of the Cervix" and "The Evolution of Cancer Control and Knowledge" respectively.

**Society News.**—Dr. Addison G. Brenizer, Charlotte, N. C., addressed the Newberry County Medical Society, Newberry, November 10, on "The Evolution of Thyroidectomy." Other speakers were Drs. Austin T. Moore, on "Fractures—Some Fundamental Principles in Their Treatment"; Roger G. Doughty, "Head Injuries," and Lucius Emmett Madden, "Coronary Thrombosis"; all are of Columbia.—Dr. Rock Sleyster, Wauwatosa, Wis., President-Elect of the American Medical Association, addressed the Columbia Medical Society November 14 on "Medical Problems of the Day." Dr. George Bolling Lee, New York, addressed the society October 10, on "Chorio-Epithelioma" and Dr. James Heyward Gibbes, Columbia, on "Tick Paralysis as Indicative of Growing Menace from Ticks as Carriers of Disease."

### TEXAS

**Annual Registration Due January 1.**—Every practitioner of medicine and surgery holding a license to practice in Texas is required by law to register annually on or before January 1 with the state board of medical examiners and at that time to pay a fee of \$2. If a practitioner fails to renew his registration within sixty days after January 1 his license is suspended.

### WEST VIRGINIA

**Personal.**—Dr. Norman G. Angstadt, New Martinsville, has been appointed health officer of Wetzel County to succeed Dr. John B. Hozier, acting health officer during the past year.—Dr. William A. Bevacqua, Charleston, has been appointed health officer of Parkersburg and Wood County to succeed Dr. Arthur D. Knott, Parkersburg, resigned.—Dr. David B. Ealy, Moundsville, was elected to the state senate in the November election.

**Society News.**—Dr. Edward M. Livingston, New York, addressed the Kanawha Medical Society, Charleston, October 11, on "Abdominal Pain."—Dr. Wilbur E. Hoffman, Charleston, addressed the Monongalia County Medical Society, Morgantown, October 4, on "Ruptured Uterus."—Dr. Vernon L. Peterson, Charleston, was the speaker at a meeting of the Raleigh County Medical Society, Beckley, October 20, on silicosis.—The Wood and Kanawha county medical societies held a joint meeting October 20 at the Spencer State Hospital. Drs. Jacob J. Alpers and Mark Thumin of the hospital staff read papers on shock therapy of mental patients. Dr. George D. Johnson, superintendent of the hospital, entertained the visiting physicians and the state board of control at a dinner in the hospital dining room.

## GENERAL

**Outbreaks of Tularemia.**—Twelve deaths from tularemia have been reported in Illinois since the hunting season opened November 10; according to the newspapers of December 12. More than 250 cases have been reported. The sale and transportation of rabbits have been barred in East St. Louis, where twenty-six cases were reported within fifteen days. In Indiana fifty-five cases were reported in the first ten days of December, as compared with thirty-three cases during the entire month in 1937. Cases have been reported in Iowa and Ohio, although Illinois is said to be leading in prevalence.

**Symposium on Glycols.**—The pharmacy section of the American Association for the Advancement of Science will present a special session on glycols December 27 at the meeting in Richmond, Va. The speakers will be:

Frank C. Whitmore, Ph.D., State College, Pa., Chemistry of the Glycols.  
Herbert O. Calvery, Ph.D., chief pharmacologist, Food and Drug Administration, U. S. Department of Agriculture, Washington, D. C., Pharmacology of the Glycols.

Mr. H. B. McClure, Carbide and Carbon Chemicals Corporation, Industrial Application of the Glycols.

Andrew G. DuMez, Ph.D., Baltimore, Pharmaceutical Uses of the Glycols.

Discussion will be opened by Drs. Harvey B. Haag, Richmond, and Michael G. Mulinos, New York.

**Society News.**—The National Gastroenterological Association announces that it has taken an office with its official publication, the *Review of Gastroenterology*, at 1819 Broadway, New York.—The sixteenth annual meeting of the American Orthopsychiatric Association will be held in New York at the Hotel Commodore, Feb. 23-25, 1939. Dr. Norville C. LaMar, New York, is the secretary.—The Pacific Coast Surgical Association will hold its next annual session in San Francisco, Oakland and Del Monte, March 28-31, 1939. Dr. Harry Glenn Bell, University of California Hospital, San Francisco, is the secretary.—Dr. Jennings C. Litzenberg, Minneapolis, was chosen president-elect of the Central Association of Obstetricians and Gynecologists at its annual meeting in Minneapolis in October. Dr. Ralph A. Reis, Chicago, became president and Dr. Thomas B. Sellers, New Orleans, was elected vice president. Dr. William F. Mengert, Iowa City, was reelected secretary.

**Posthumous Award of Sedgwick Medal.**—The American Public Health Association at its meeting in Kansas City October 25-29 awarded its Sedgwick Medal posthumously to Dr. Wade Hampton Frost, professor of epidemiology at Johns Hopkins University School of Hygiene and Public Health, Baltimore, who died May 1. Dr. Frost served as dean of the Johns Hopkins school of hygiene from 1931 to 1934 and had been professor since 1921. He was associated with the U. S. Public Health Service from 1905 to 1929. During the World War he was director of the bureau of sanitary science of the American Red Cross. In a statement at the meeting in Kansas City Dr. Haven Emerson, New York, on behalf of the medal committee, said: "While his illuminating contributions in the fields of poliomyelitis, influenza, diphtheria and tuberculosis stand high among the classics of epidemiology, perhaps his planning, direction and guidance of the stream pollution laboratory at Cincinnati will prove to have been his most abundant legacy to the expanding fields of the theory and practice of public health."

**Southwestern Medical Association.**—The annual session of the Southwestern Medical Association was held in El Paso October 28-29 with headquarters at the Hotel Cortez. The guest speakers were:

Dr. Charles A. Bahn, New Orleans, Prevention of Blindness from the Standpoint of the General Practitioner; Practical Ophthalmic Advances for the General Physician.

Dr. Horton R. Casparis, Nashville, Public Health Aspects of Childhood Tuberculosis; Medical Aspects of Healthy Child Behavior; Allergy in Children.

Dr. George T. Caldwell, Dallas, Texas, Estimation of Kidney Function; Pathology of Vitamin Deficiencies.

Dr. Raymond W. McNealy, Chicago, Preoperative Management of the Jaundiced Patient; Dietary Deficiencies in Surgical Patients; Management of Blood Vessel Injuries and Their Sequelae.

Dr. Edward H. Rynearson, Rochester, Minn., Complications of Diabetes; Present Day Methods of Treating Goiter; Recent Advances in Endocrinology.

Dr. Curtice Rosser, Dallas, Texas, Diagnostic Criteria of Rectal Cancer; Rational Management of Hemorrhoids; Rational Management of Minor Anal Conditions.

Chauncey D. Leake, Ph.D., San Francisco, Antiseptic Agents; Epinephrine, Ephedrine and Their Derivatives; Art in Medicine.

Dr. Orville E. Egbert, El Paso, was chosen president-elect of the association and Dr. Howell S. Randolph, Phoenix, Ariz., was installed as president. Drs. Ralph W. Mendelson, Albuquerque, N. M., and Jesse D. Hamer, Phoenix, were elected vice presidents and Dr. Maurice P. S. Spearman, El Paso, Texas, is secretary.

**Foundation for Infantile Paralysis Extends Organization.**—A new plan of organization in county units was adopted by the National Foundation for Infantile Paralysis at a meeting of its trustees and officers in New York November 10. Permanent county chapters are to be organized as fast as possible after the campaign for funds, which will reach its climax on President Roosevelt's birthday, Jan. 30, 1939. In addition to the plan for field organization, the officials of the foundation decided that the funds raised this year will be divided on a 50-50 basis, half to be sent to the national committee and half to be retained in the counties where the money is raised. It is planned that county chapters will work closely with the national committee in helping victims of poliomyelitis, in disseminating knowledge of diagnosis and treatment and in emergencies in times of epidemics. Funds left in the counties will be held as trust funds for the account of the national foundation and will be administered under general rules and regulations laid down by the national foundation, according to the announcement, but within those limitations expenditures will be in the discretion of the local chapter or unit.

**Low Tuberculosis Mortality Rate.**—The National Tuberculosis Association, which opened its thirty-second annual sale of Christmas seals Thanksgiving Day, announces that the death rate from tuberculosis dropped from 55.5 per hundred thousand in 1936 to 53.5 in 1937, the lowest ever reported. The 1936 rate was the highest in ten years, an increase attributed to the cumulative effects of the depression. In 1936 71,239 persons died of tuberculosis and in 1937 the number

was 69,151. Fifteen states showed an increase over 1936, but this was more than balanced by decreases in thirty-two states. Michigan's rate remained the same and the District of Columbia showed a decrease. Among the states in which notable decreases were reported were: Arizona, 258.5 from 271.2 the previous year; Maine, 33.5 from 40.6; New Hampshire, 28 from 33.9; North Carolina, 54.8 from 60.8; Tennessee, 84.7 from 89.6, and Virginia, 59.4 from 64.2.

Wyoming reported a rate of 18.3, the lowest of any state, though it was an increase from 15 reported in 1936. The highest rates were in Arizona and New Mexico, with 258.5 and 113.3 respectively, followed by the District of Columbia with 94.9. Case finding activities increased in twenty-seven states, according to the report. Thirteen states and the District of Columbia exceeded the standard ratio of two new cases reported to each death in any year. The states were Connecticut, Idaho, Illinois, Maryland, Massachusetts, Michigan, Minnesota, Montana, New Jersey, New Mexico, New York, Oregon and Washington.

### Dr. McIntire Appointed Surgeon General of Navy

President Roosevelt announced November 29 the appointment of Dr. Ross T. McIntire, who for five years has been White House physician, as surgeon general of the U. S. Navy, with the rank of rear admiral. Dr. McIntire was first commissioned in the navy in 1917 and his rank was that of commander, although he was temporarily a captain at the time of his latest appointment. The President has not yet announced the appointment of the new White House physicians, of whom there will be two from now on, according to newspaper reports. Dr. McIntire was born in Salem, Ore., Aug. 11, 1888, graduated from the Willamette University Medical Department, Salem, in 1912 and was first commissioned in the medical corps of the navy April 4, 1917. Prior to assignment to duty as White House physician he was in charge of the eye, ear, nose and throat service at the Naval Hospital in Washington. As Surgeon General he succeeds Dr. Percival S. Rossiter, who retires from active service because of the age limit. In reaching the rank of rear admiral, Dr. McIntire, in service parlance, was jumped over the heads of thirty-four commanders and eighty-four captains. A native of Shepherdstown, W. Va., Dr. Rossiter has been a member of the medical corps of the U. S. Navy since 1903. He was a member of the U. S. Naval Mission to Brazil, 1922-1926; commanding officer of the Brooklyn Naval Hospital, 1929-1932, Washington, D. C., Naval Hospital, 1932-1933. In 1933 he became surgeon general. He graduated at the University of Maryland School of Medicine, Baltimore, in 1895.

#### The Public Health

The report for 1937 of the chief medical officer of the Ministry of Health, which has just been published, shows that the birth rate was 14.9 per thousand living, a slight rise on 14.8 for 1936 and 0.5 above that for 1933, which was the lowest on record. The infant mortality was 58 per thousand births, against 59 for 1936, but one point higher than the exceptionally low figure of 57 in 1935. The five principal killing diseases remain the same as for many years and in the same order: (1) diseases of the heart and circulatory system, (2) malignant disease, (3) respiratory diseases, (4) diseases of the nervous system, (5) tuberculosis. But if the diseases are arranged to show the principal killing diseases in the years of working life from 15 to 65 years, tuberculosis takes the third place and diseases of the nervous system the fifth. There has been a decline in the incidence of lethargic encephalitis and scarlet fever but an increase in that of cerebrospinal fever, diphtheria, dysentery, influenzal pneumonia and acute poliomyelitis. The maternal mortality continues to fall, being 3.13 against 3.65, 3.94 and 4.41 in 1936, 1935 and 1934. Puerperal sepsis accounted for 0.94 per thousand, leaving 2.19 for other causes. There is evidence that fresh infection with syphilis is declining. There is no evidence that cancer is becoming less prevalent. More than half as many males were killed by injury as by all the infectious diseases taken together, and a large proportion of these violent deaths occurred on the roads. Statistical inquiry has revealed that there are accident-prone just as there are sickness-prone persons, i. e., persons for whose abnormal sickness rate no physical grounds can be assigned and malingering can be excluded. A great extension has been made of the scheme of graduate education for panel physicians, who it is intended will receive a free course every five years. Not only will the course be paid for but also traveling and subsistence costs and the cost of a locum tenens when one is necessary.

#### Rectal Ulceration Due to Cancer of Cervix

When new drugs are found valuable in treatment it is only later and gradually that their possible toxic effects become evident. The same statement holds true for radiotherapy, which has proved such an important advance in the treatment of cancer. It is only recently that it has been discovered that the radium treatment of cancer of the cervix uteri may produce chronic ulceration of the rectum. But little has been published on the subject, and the pathology of the condition has not been described. During the tenure of a research scholarship at the Christie Hospital and Holt Radium Institute, Manchester, Mr. T. F. Todd has had personal experience in thirty-four cases of chronic ulceration of the rectum in 800 cases of cancer of the cervix treated by radium. In a report to the North of England Obstetrical and Gynaecological Society he stated that this reaction was frequently overlooked and several cases were referred after previous radium treatment elsewhere for what was misdiagnosed as cancer of the rectum. The cases were of two types: 1. A lesion restricted to the anterior rectal wall, usually at the level of the cervix uteri, forming a mobile ulcerated mass from 3 to 5 cm. in diameter and resembling an operable carcinoma. 2. A rectal ulceration similarly situated, but accompanied by gross perirectal induration and formation of a hard fixed mass enveloping the rectum and anchoring it to the sacrum, resembling advanced inoperable cancer with extensive extrarectal spread. In its early stage the

rectal ulceration took the form of acute proctitis. The reaction might be due to overdosage from slipping of the radium applicators and their approximation to the rectum in the posterior fornix or to retroversion which allowed the intra-uterine applicator to project against the rectum. The main factor appeared to be obliteration of blood vessels from the high dosage.

The symptoms usually began after from six to nine months' treatment. They included tenesmus, melena and severe pain. Spontaneous healing was the rule, but stenosis of the rectum might occur and require colostomy. The incidence of the ulceration could be reduced by precautions to avoid misplacement of the vaginal applicators and overdosage and by nursing patients in the prone position. In four cases presacral neurectomy was done for the relief of pain and acceleration of healing. It was suggested that it might act as a prophylactic against massive perirectal fibrosis by producing vasodilatation.

#### Toxic Effects of Sedormid

Attention has recently been directed to the toxic effects of the hypnotic sold under the name of sedormid (allyl-isopropyl-acetyl-carbamide). A number of cases of purpura haemorrhagica have been recorded. In the *Lancet*, Miller and Rosenheim suggest that it is a dangerous drug. They report a case in which a woman physician aged 26 was given two tablets of sedormid nightly while convalescent after thyroidectomy. She found it an excellent hypnotic, but after six weeks' use a widespread purpuric rash appeared. Though the drug was stopped she became acutely ill and the purpura was complicated by severe epistaxis. Her blood films showed almost complete absence of platelets, and despite three transfusions the hemoglobin fell in ten days to less than 30 per cent. Two further transfusions were necessary before the platelet counts began to increase. Discussing two cases of severe thrombocytopenic purpura due to the use of sedormid for insomnia, in the *British Journal of Dermatology*, the editor (Dr. A. C. Roxburgh) states that he has seen two cases of eruption, not purpuric, due to this cause. Both patients were women between 60 and 70 years of age. In one there was a red circinate eruption on the neck, cheeks, upper part of the back, sternum and backs of the hands. In the other patient there was a red scaling patch measuring 1 by 1½ inches on the back of the forearm, raised about one-fourth inch. It took several weeks to disappear. In both patients the eruption ceased after the sedormid was stopped but it recurred in the first patient when she resumed the drug.

#### The British Heart Journal

With the beginning of the new year the British Medical Association will publish a quarterly journal devoted to disease of the heart and circulation under the title of the *British Heart Journal*. This journal, which is being published at the request of the Cardiac Society of Great Britain and Ireland, will be edited by the cardiologists Dr. Maurice Campbell and Dr. Evan Bedford. The *British Medical Journal* states that, as diseases of the heart and circulatory system are the first of the principal causes of death at all ages in this country, it is a matter of surprise that such a journal is not already in existence. This does not overlook *Heart*, which for many years was edited by Sir Thomas Lewis and held a unique position among the medical periodicals of the world—a position still maintained with change of title to *Clinical Science* but happily without any change of editor. The research in experimental medicine that is carried out by Sir Thomas Lewis and is reported in this journal is of supreme importance to medicine and represents a field that probably will be only incidentally surveyed in the *British Heart Journal*. The new periodical will deal with work more concerned with the everyday diagnosis and treatment of patients and so will be of immediate value to the practicing physician. The appeal will be to the cardiologist.

ogists, both at home and in other countries, but the journal is commended to all physicians "to whom the stethoscope of Laënnec has become the badge of their tribe." In form it will be similar to the other two special journals published by the *British Medical Association*. The subscription will be \$6 a year.

### Recovery from Meningococcic Meningitis After the Use of Sulfanilamide

At the October 14 meeting of the Société médicale des hôpitaux of Paris Dr. R. A. Marquezy and his associates reported two cases of meningitis due to the meningococcus in which recovery followed the administration of sulfanilamide alone. In all cases which have previously been reported, chemotherapy was preceded by serotherapy. The authors cited a study by Muraz, Chirle and Queguinier (*Presse médicale*, July 16, 1938) of 397 cases of meningococcic meningitis treated during an epidemic of the disease in French Nigeria. The mortality in forty-nine cases in which serum alone was given was 22.44 per cent; in twenty-three cases in which serum and sulfanilamide (by mouth) were given, 8.7 per cent; in thirty-nine cases in which sulfanilamide given by mouth was preceded by one intraspinal injection of the drug, 15.38 per cent; in ten cases in which sulfanilamide given by mouth was preceded by two intraspinal injections of the drug, no deaths, and in 271 cases in which sulfanilamide given by mouth was the only therapy, 10.7 per cent.

In both of the cases reported by Marquezy and his associates, only sulfanilamide was given. The first patient, a boy aged 16, was given 7 Gm. a day by mouth for the first seven days and gradually decreasing amounts during the next twelve days. In addition, an intraspinal injection of an 0.8 per cent solution was given daily for fifteen days, the average amount being 10 cc. The second patient, a man aged 25, was given sulfanilamide only by mouth. Intraspinal administration is preferable at the onset as it secures a concentrated solution of the drug in the spinal fluid at the earliest possible moment.

In the discussion Dr. Weill-Hallé reported an additional case with recovery, in which only sulfanilamide was employed. Dr. Marquezy stated that sulfanilamide had not been found to be of any value in a personally observed case of pneumococcic meningitis. Dr. Benda suggested the use of sulfanilamide-pyridine in such cases.

### French Otorhinolaryngologic Congress

The president of this year's meeting of the French Otorhinolaryngologic Congress, held in Paris October 24-26, was Dr. le Mée. The subject of the first report, by Drs. Collet and Mayoux of Lyons, was auricular tuberculosis. Although it is generally taught that from 5 to 10 per cent of the cases of chronic otitis media and mastoiditis are of tuberculous origin, the authors believe that this percentage is far too low, because in many cases the disease is not correctly diagnosed. Tuberculous otitis is at times observed clinically as an associated condition with pulmonary tuberculosis. Usually, however, the condition occurs independent of pulmonary localization. The clinical picture then differs considerably from that observed when it is an associated condition. Most commonly there is a history of an acute onset, resembling in every respect the clinical picture in cases of ordinary nontuberculous otitis. With children, tuberculous otitis should be thought of if there has been exposure to tuberculous adults, if the granulation tissue formed after a mastoid operation is flabby and pale and contains caseous particles, and if a fistula persists after mastoidectomy. In all such cases a search for underlying tuberculosis must be made with the aid of the guinea pig inoculation method. This had confirmed the clinical diagnosis in twenty-

two cases. The prognosis, unless pulmonary lesions exist, is far more favorable than is generally believed. The treatment is surgical followed by heliotherapy and actinotherapy. As to the pathogenesis, the authors were of the opinion that the infection was primary in the nasopharynx and involved the middle ear by way of the eustachian tube.

## TUMORS OF HYPOPHARYNX AND LARYNX

The subject of the second report, by Drs. Huët of Paris and Péri of Algiers, was roentgenologic exploration of tumors of the hypopharynx and larynx. The first objective in exposing films is to obtain profile views of the hypopharynx and larynx. The second objective is to secure anteroposterior views. The various technical methods to secure satisfactory exposures were described in detail. At the Paris Cancer Institute it has been found that 60 per cent of tumors of the hypopharynx originate in the piriform sinuses. Some are very radiosensitive and show but little tendency to extension, whereas others are very malignant. The remainder of this thorough review of the roentgenologic methods of diagnosis contained chapters on the search for endolaryngeal tumors and lesions of the cartilages.

## POLYPS OF LARYNX; MENINGITIS

Drs. Piquet and Boury of Lille reported four cases of malignant changes in polyps of the larynx; hence every papilloma should be regarded as a potential cancer. Dr. Leroux-Robert said that a polyp was a purely inflammatory lesion and must be distinguished from a papilloma. The latter was a precancerous condition, but this was not true of a polyp. This point of view was confirmed by Professor Lemaître of Paris.

Dr. Marcel Ombredanne of Paris reported three cases of streptococcic meningitis of otitic origin in which recovery had followed the use of a preparation similar to sulfanilamide. In only one of the three cases had the drug been employed exclusively, i. e., no operation performed. Those who took part in the discussion of this paper believed, however, that it is advisable always to operate and to give the drug as an adjuvant.

## BERLIN

(From Our Regular Correspondent)

Nov. 8, 1938.

### The Extent of Poliomyelitis in Germany

For several years a number of cases of epidemic poliomyelitis have been reported each summer from some part of the German reich. The locality affected varies from year to year. In general a year of severe epidemic is succeeded by several years during which the erstwhile stricken community remains more or less spared from the disease. An official survey just published by the national health bureau traces the incidence of the disease in Prussia since 1909 and in the entire reich since 1924. In 1909 a great wave of poliomyelitis occurred in Germany. Yet as soon thereafter as 1910 poliomyelitis had become a fairly rare disease. Not until 1926 did the morbidity rise again and in 1927 it attained a new peak with 2,840 cases. In 1928 the number of new cases again dropped to one third of the corresponding number for 1927. Thereafter the morbidity slowly increased from year to year until 1932. The latter year was marked by a severe epidemic (the most severe thus far, the cases numbering 3,869). In 1933 the number receded to one-third that of the previous year. Subsequently and down to date it has developed a gradual upward trend from one year to another. There were 2,256 cases reported in 1936 and 2,723 in 1937. According to these official statistics the 1938 figure will be higher than that for 1937.

In other countries also greatly increased incidences have been noted in recent years, particularly in the Scandinavian lands since 1934 and in Austria, Switzerland and Italy since 1936. At present an increased morbidity is reported from the Nether-

lands, whereas in the other foreign countries mentioned no especially notable increases have been reported during the current year.

A detailed survey shows that the region of highest morbidity within the reich changes from one year to the next in a desultory manner. An explanation of the erratic fluctuations in the waves of anterior poliomyelitis is to be found in the immunity against repetition of infection conferred by recovery. Thus only after a new generation of children has arisen will the contagion again encounter a large number of susceptible persons. However, the morbidity of poliomyelitis even in times of epidemic never suffices to immunize the entire population, since the disease is, after all, rare. This is shown by the following comparison: In 1937 there were 2,723 cases of poliomyelitis against 146,733 cases of diphtheria. Accordingly it must be that the majority of children either are not susceptible to infection by the agent of poliomyelitis or do not react to this infection in such a way as to produce the typical disorder with its concomitant paralysis. Even the so-called silent infections can confer immunity against later contagion. "Silent" infections are much more frequent than the forms that run a severer course.

With the end of the short-lived seasonal wave the local prevalence of the contagion tends to subside and soon disappears almost completely. The location and severity of the next year's epidemic cannot be foretold. A strong impetus has recently been given to investigation of the many as yet unsolved problems relative to ways and means of combating poliomyelitis. A new plan of therapy, based on uniform points of view, has been instituted in the hospitals of Berlin and of Hamburg. The experimental studies are concerned with the determination of the protective value of convalescent serum. Attempts have also been made to determine for how long and in what quantity protective substances are present in human beings following recovery from poliomyelitis as well as the protective value of the serum of healthy persons from the environment of patients with poliomyelitis. Finally, closer studies of the virus have been attempted by its cultivation. Only within the next few years will the results of this research be evaluated.

#### The Number of New Medicaments in Germany

The association of manufacturers of chemical-pharmaceutic preparations, an organization that represents thirty-seven leading German firms, reports that during 1935, 1936 and 1937 a total of 174 new specialties were placed on sale, whereas 108 specialties were withdrawn from the market. Accordingly the total number of these firms' pharmaceutic products on the market during the past three years increased by sixty-six. On April 1 these firms had 1,314 specialties on the market; if particular medicinal forms are considered, this total reaches 1,969.

Judging by the flood of pharmaceutic products in the German market, the quoted figures suggest that pharmaceutic houses both inside and outside the manufacturers' association bring out a vast number of so-called pharmaceutic agents (*arzneimittel*), which for the most part contain no new principle but rather—and this is still considered good form—merely represent the same or similar products under new names. In any event the regulation of the pharmaceutic industry, long urged by representatives of the medical profession, has not yet taken place, even with regard to the public declaration of every pharmaceutic product prescribed by a physician.

#### The Importance of Ewe's Milk in the Diet

Ewe's milk in the diet was the object of investigations undertaken by the Breslau University institute of animal husbandry and milk economy, the experimental research station for animal husbandry at Kraftborn and the Breslau Municipal Hospital for Nurslings and Infants. The principal investigators were

W. Zorn, F. Richter and C. Wiener. With respect to the importance of ewe's milk in the national food economy it was estimated that there is an annual world yield of 5 billion liters, as against 17 billion liters of goat's milk and 270 billion liters of cow's milk. Europe produces 44 per cent of all ewe's milk and thus stands far ahead of Asia and Africa. Of all European countries Italy is the largest producer of ewe's milk, the yield there being 620 million liters yearly; Germany produces only 20 million liters of ewe's milk yearly (as against 24 billion liters of cow's milk).

To determine the suitability of ewe's milk as a food for nurslings, the investigators carried on feeding experiments, the results of which are reported in the journal *Ernährung*. The quality of ewe's milk with respect to its ingredients is greatly dependent on the state of lactation, even in comparison with cow's milk and human milk. Ewe's milk is far superior to human milk and cow's milk in fat, protein and mineral content and consequently in caloric content. Further questions studied were whether nurslings previously nursed by the mother ought to be put on ewe's milk, whether children who have been receiving cow's milk should be given ewe's milk instead and whether dyspepsia in nurslings can be dietetically treated with ewe's milk. It was found that artificial feeding of nurslings with ewe's milk is readily practicable and that it is even more easily accomplished and leads to better results than feeding with cow's milk. Even if the nurslings were suddenly taken off cow's milk and placed on ewe's milk, the substitution was always satisfactorily accomplished, and if the babies had been affected with acute gastro-enteric catarrh when fed with cow's milk quick remission of this dyspepsia took place when they were fed with ewe's milk.

#### Appointment to Chair of Psychiatry at Berlin

A short time ago Prof. Karl Bonhoeffer, since 1912 ordinarius in psychiatry at Berlin and now 70 years old, was retired from his post. Bonhoeffer had an excellent record as director of the clinic for psychiatric and nervous diseases at Berlin University. He performed pioneer work in the fight against alcoholism, and his views on the treatment of alkaloid addictions was fundamentally accurate. He also originated the doctrine of "exogenic reaction types."

Prof. Max de Crinis, erstwhile ordinarius in psychiatry at Cologne, has been appointed to succeed Professor Bonhoeffer. De Crinis is 49 years old. An Austrian by birth, he served formerly as extraordinary professor at the University of Graz, Austria. In 1934, after his Nazi sympathies had cost him his post in Graz, he was called to Cologne. He has worked on epilepsy and the histopathology of intoxications as well as on other histologic problems concerning nerve tissue.

#### Prof. Franz Volhard Has Retired

The professor of internal medicine at the University of Frankfort on the Main has been retired, having reached the age limit of active service, 68 years. A pupil of Riegel at Giessen, Volhard first served as senior physician in large hospitals at Dortmund and at Mannheim. In 1918 he became ordinarius in internal medicine at Halle on the Saale and in 1927 he assumed a similar post at Frankfort on the Main. His greatest contributions to internal medicine were above all in the field of gastric, circulatory and kidney disorders. In 1899 he discovered the lipolytic ferment of the stomach. He engaged in a vast amount of research on hypertonia, especially the interrelation of hypertonia and diseases of the circulation and the kidneys. Volhard has become best known for his work in the field of kidney diseases. One need only recall the Volhard specific gravity test of renal function. Volhard's treatise on Bright's disease, written in collaboration with Fahr, has enjoyed wide dissemination and recognition. The testing of renal function has been vastly improved and promoted by Volhard.

## AUSTRALIA

(From Our Regular Correspondent)

## The People and Socialized Medicine

After a hard fight and bitter contest, the labor government in New Zealand, despite the well organized campaign and extensive publicity of the nationalist opposition, has won a sweeping victory at the polls. At the last elections in 1935, labor came into office with a large majority, not because of its own policy but because it reaped the benefit of a popular reaction against the nationalist government. The main issue of the elections was the character and extent of social—or socialist—legislation. Mr. Savage took his stand on the social security act (in which provision is made for universal free medical service, increased pension allowances and unemployment insurance) and extended government control of banking policy. The opposition championed private enterprise against labor socialism, attacking the proposed extension of social services as financially unsound and advocating a more modest scheme of social benefits. In this it had the active support of the British Medical Association in New Zealand, which association indeed played a most active part in the election campaign. The people, however, have recorded a heavy vote in favor of state control. The official reaction of the medical profession to this position is uncertain. Before the elections the association in New Zealand had broken off all discussion with the government on health insurance matters, after the government's rejection of the association's proposals.

## Law Relating to Abortion

The artificial interruption of pregnancy by a medical practitioner in a recent case of incest in South Australia has occasioned much discussion in medical and other circles as to the legal grounds for the termination of pregnancy after rape or incest. The law in this country is as follows: "Any person who, with intent to procure the miscarriage of any woman, whether she be or be not with child, unlawfully administers to her, or causes to be taken by her, any poison or other noxious thing, or unlawfully uses any instrument or other means whatsoever with the like intent shall be guilty of felony, and liable to imprisonment for life." The use of the word "unlawfully" implies that Parliament had in mind that such an act might be done "lawfully" if it was necessary to preserve the life of the mother, which in practice means her health and sanity, for, without either, life is worthless. The judge in the Bourne case in England, addressing the jury, said that it was obvious that the act if done by skilled persons without risk to the patient and on purpose to save the life of the mother must be lawful. The law did not permit the termination of pregnancy except for the purpose of preserving the life of the mother, but those words ought to be construed in a reasonable sense. If the physician was of the opinion, based on reasonable grounds and on adequate knowledge, that the continuance of pregnancy would probably make the woman a physical or mental wreck, the act was lawful. The law, however, does not permit the termination of pregnancy for humanitarian or eugenic reasons.

In the recent case of incest, the medical practitioner concerned brought the circumstances to the notice of the council of the South Australian Branch of the British Medical Association. After giving evidence in the police court that the girl was twenty-six weeks pregnant, he, who had been subpoenaed, requested the magistrate to receive from him a recommendation to be forwarded to the branch council. In this it was recommended that, in consideration of the very grave doubt as to the future mentality of the child to be born and the danger to the future health and mental state of the child mother, physicians learned in such matters should confer with a view to ensuring nonsurvival of the infant. The council, however, has emphatically asserted in a public statement that it is not its province officially to advise members of the branch on the professional

care of individual patients. It was pointed out to the practitioner concerned how the opinion of specialists might be obtained to determine whether the birth of the girl's child was fraught with danger to the life of the mother. No further action by the council was deemed necessary. Although it is realized by the council that public opinion is immensely and medical opinion is much in favor of the legal termination of pregnancy in cases of rape and incest, it has not yet considered what action, if any, should be taken in respect to alteration of the law concerning abortion.

## Marriages

JOHN RICHARD HEATON, Hoopeston, Ill., to Miss Edyth Eleanor Clawson of La Fayette, Ind., October 29.

ROBERT A. HARE, Baltimore, to Miss Anne Lee Mead of Berkeley, Calif., in Alexandria, Va., October 23.

EUGENE LLOYD WENK, Cloutierville, La., to Miss Cammie Henry of Melrose in Alexandria, September 23.

ALFRED DEADERICK DOAK, Shelbyville, Ky., to Miss Evelyn Marie Cowan of Fayetteville, Tenn., in October.

LEWIS WILLIAM HAGNA, Marion, N. C., to Mrs. Evelyn Mentzer Innes of Huntington, Pa., in October.

JAMES GILBERT MASON WEYAND, Rochester, Pa., to Miss Susan Gallup of Beaver Falls, October 22.

RICHARD E. HOUSNER, Richland Center, Wis., to Miss Ardyce Kotvis of Hillsboro, October 30.

ROBERT WILLIAM BARRETT, Lexington, Mass., to Miss Alice Frances McNamara of Allston recently.

HERBERT PAUL DEXHEIMER, O'Fallon, Ill., to Miss Doris McGilligan at Tower Hill, October 29.

WILLIAM FREDRIC DELP to Miss Dorothy Elizabeth Wallner, both of Pulaski, Va., November 15.

DANTE PETER DAPOLONIA, New York, to Miss Buena Jones of West Point, Ga., September 30.

SAMUEL A. FREITAG to Miss Alice Elizabeth Kimball, both of Janesville, Wis., November 4.

ARTHUR ROWELL DAHLGREN, Atlanta, to Miss Jane Hartzog of Los Angeles, October 30.

WILLIAM R. BAKER to Miss Mary Corine Jaillet, both of Atlanta, Ga., in September.

OWEN C. CLARK, Oconomowoc, Wis., to Miss Grace Gasper of Waukesha, November 5.

LESTER J. BUIS, Pender, Neb., to Miss Isabel Connolly of Muncie, Ind., August 14.

GLENN S. EDGERTON, Hickory, N. C., to Miss Sylvia Steele of Statesville in October.

RALPH V. EVERLY, Indianapolis, to Miss Ruth L. Black of Brownstown, October 28.

LAWRENCE H. DONATH to Miss Mary Masters, both of Lake Geneva, Wis., October 1.

HENRY SARGENT HOWARD to Miss Louise Flora, both of Peoria, Ill., October 20.

GILBERT W. BENJAMIN, Baltimore, to Miss Doris Sundmacher at Radnor, Pa., recently.

CHARLES E. WALL to Miss Dorothy Burns, both of Manitowoc, Wis., October 8.

CLARK E. BAKER, Marion, Ill., to Miss Mary Rodd of St. Louis, September 10.

RAYMOND R. REMBOLT to Miss Mac Street, both of Lincoln, Neb., September 11.

GEORGE H. WEGMANN JR. to Miss Betty Sacia, both of Milwaukee, October 15.

RALPH VINJE to Miss Evangeline Kelley, both of Bismarck, N. D., October 27.

RALPH COHEN to Miss Paula Doris Josephie, both of New York, October 14.

TALCOTT BATES to Miss Margaret S. Pardee, both of New York, October 13.

SAMUEL BISHOP HUGHES, Wildwood, N. J., to Miss Anne Weber recently.

JOHN SEARLE GIFFIN to Miss Betty Burk, both of Waterloo, Iowa, October 8.

SIDNEY BERMAN to Miss Beatrice E. Kay, both of Detroit, October 22.

## Deaths

**James Allen Jackson** ☉ Danville, Pa.; Jefferson Medical College of Philadelphia, 1906; Member of the House of Delegates of the American Medical Association, 1932-1937; fellow of the American College of Physicians; member of the American Psychiatric Association; teacher of neurology and psychiatry, Temple University School of Medicine, 1918-1920; superintendent of the Danville State Hospital; formerly associate editor of the *Atlantic Medical Journal*; editor of the *Mental Health Bulletin* published by the state hospital; in 1929 received the honorary degree of doctor of science from Bucknell University; aged 54; died, December 1, in the Jefferson Hospital, Philadelphia, of leukemia.

**Sterling Newton Pierce** ☉ Los Angeles; College of Physicians and Surgeons, Los Angeles, 1917; assistant clinical professor of obstetrics and gynecology, University of Southern California School of Medicine; member of the Pacific Coast Society of Obstetrics and Gynecology; fellow of the American College of Surgeons; on the staffs of the Cedars of Lebanon, Los Angeles General, California, Hollywood Clara Barton Memorial and the White Memorial hospitals; aged 51; died, September 30, of injuries received in an automobile accident.

**Chauncey Vandever Umsted**, Worcester, N. Y.; University of Pennsylvania Department of Medicine, Philadelphia, 1908; during the World War served as a member of an examining board; for many years deputy health commissioner in Yonkers; at one time visiting physician to St. Joseph's Hospital, Yonkers; aged 53; died, September 14, of heart disease and nephritis.

**William Henry Chase**, Montreal, Que., Canada; Dalhousie University Faculty of Medicine, Halifax, N. S., 1922; member of the American Association of Pathologists and Bacteriologists and the American Association of Neuropathologists; lecturer and Douglas Fellow in pathology at McGill University Faculty of Medicine and curator of the museum; aged 43; died, October 20.

**Russell Ebenezer Atchison**, Northville, Mich.; University of Michigan Homeopathic Medical School, Ann Arbor, 1900; member of the Michigan State Medical Society; for many years superintendent of the University of Michigan Homeopathic Hospital, Ann Arbor; aged 68; died, October 18, in the University of Michigan Hospital, Ann Arbor, of Parkinson's syndrome.

**Glenn Levi Whiting** ☉ Canisteo, N. Y.; University of Buffalo School of Medicine, 1904; past president of the Steuben County Medical Society; served during the World War; county coroner; member of the board of education; aged 62; on the staff of the Bethesda Hospital, Hornell, where he died, September 8, of bacillary dysentery and pernicious anemia.

**Andrew Macphail**, Montreal, Que., Canada; McGill University Faculty of Medicine, Montreal, 1891; formerly professor of the history of medicine at his alma mater and professor of pathology at the University of Bishop College Faculty; served during the World War; formerly editor of the *Canadian Medical Association Journal*; aged 73; died, September 23.

**Stephen Thomas Quinn** ☉ Elizabeth, N. J.; University of the City of New York Medical Department, 1897; fellow of the American College of Surgeons; on the staffs of St. Elizabeth's Hospital and Elizabeth General Hospital; served during the World War; aged 71; died, September 18, in the Sisters Hospital, Waterville, Maine, of bronchopneumonia.

**Edgar Nathan Cowan**, Merchantville, N. J.; Medico-Chirurgical College of Philadelphia, 1916; formerly assistant professor of biochemistry at the Medico-Chirurgical College, Graduate School of Medicine, University of Pennsylvania, Philadelphia; served during the World War; aged 58; died, October 24, of chronic nephritis and uremia.

**Nathaniel Ross** ☉ Wilkes-Barre, Pa.; Jefferson Medical College of Philadelphia, 1892; past president of the Luzerne County Medical Society; served during the World War; for many years physician to the school district; on the staff of the Nesbitt Memorial Hospital, Kingston; aged 71; died, September 24.

**George McAlpin Liddell**, Waco, Texas; Baylor University College of Medicine, Dallas, 1909; member of the State Medical Association of Texas; served during the World War; city health officer; on the staff of the Providence Hospital; aged 54; died, October 23, of injuries received in an automobile accident.

**Frank Suggs**, San Antonio, Texas; Arkansas Industrial University Medical Department, Little Rock, 1897; at one time member of the medical reserve corps of the U. S. Army;

veteran of the Spanish-American and World wars; aged 63; died, September 10, of coronary occlusion and arteriosclerosis.

**Edwin Aid Layton**, Seattle; College of Physicians and Surgeons, School of Medicine of the University of Illinois, 1909; formerly medical missionary; for many years director of health of the public schools in Tacoma; aged 65; died, October 6, in the Emanuel Hospital, Portland, Ore., of myocarditis.

**Charles W. Famous**, Street, Md.; University of Maryland School of Medicine, Baltimore, 1901; member of the Medical and Chirurgical Faculty of Maryland; formerly member of the state legislature; aged 63; died, October 17, in the Union Memorial Hospital, Baltimore, of coronary thrombosis.

**Emory Hamlin Wood**, Salisbury Center, N. Y.; Hahnemann Medical College and Hospital, Chicago, 1881; member of the Medical Society of the State of New York; member of the board of education; for many years health officer; aged 78; died, September 18, of cerebral hemorrhage.

**John William Funck** ☉ Baltimore; University of Maryland School of Medicine, Baltimore, 1888; aged 84; for many years on the staffs of the Presbyterian, Eye, Ear and Throat Charity Hospital and the Franklin Square Hospital, where he died, October 4, of chronic myocarditis.

**Orlando W. Brownback**, Pendleton, Ind.; University of Pennsylvania Department of Medicine, Philadelphia, 1867; member of the Indiana State Medical Association; formerly health officer and member of the school board; aged 92; died, October 13, of chronic myocarditis.

**Marcus White Fredrick**, Brentwood, Calif.; Universität Leipzig Medizinische Fakultät, Saxony, Germany, 1888; member of the California Medical Association; formerly on the staff of the French Hospital, San Francisco; aged 77; died in September of chronic nephritis and uremia.

**Vestal Raul Abraham** ☉ Long Beach, Calif.; Rush Medical College, Chicago, 1913; fellow of the American College of Surgeons; served during the World War; on the staffs of the Long Beach Community, Seaside and St. Mary's Long Beach hospitals; aged 53; died in October.

**Arthur Horace Gordon** ☉ Chicago; Hahnemann Medical College and Hospital, Chicago, 1887; at one time professor of internal medicine at his alma mater; on the staffs of the Edgewater and Illinois Masonic hospitals; aged 75; died, December 2, of coronary thrombosis.

**Jacob Clarence Kanigsberg** ☉ Freeport, N. Y.; McGill University Faculty of Medicine, Montreal, Que., Canada, 1926; on the staff of the Meadowbrook Hospital, Hempstead; aged 38; died, September 20, of cerebral embolism and aortic and mitral regurgitation.

**Edward Albert Packard**, Newton, Mass.; College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1886; member of the Massachusetts Medical Society; aged 80; died, September 8, in South Harpswell, Maine, of angina pectoris.

**Frederick Henry Wetmore**, Hampton, N. B., Canada; McGill University Faculty of Medicine, Montreal, Que., 1888; at various times had been health officer of Kings County, medical inspector of schools and coroner of Kings County; aged 76; died, September 30.

**Olin Weston Daley**, White River Junction, Vt.; College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1884; member of the Vermont State Medical Society; formerly member of the state legislature; aged 75; died, October 16.

**Wendell Ambrose Jones**, Riverside, Calif.; Ohio Medical University, Columbus, 1898; member of the California Medical Association; city and county health officer; served during the World War; aged 64; died, September 20, of cerebral hemorrhage.

**John Lawrence Loftus**, Old Forge, Pa.; Medico-Chirurgical College of Philadelphia, 1912; served during the World War; for many years member of the school board; on the staff of the Taylor Hospital, Scranton; aged 51; died, September 29.

**Albert Hadley Cantril** ☉ Portland, Ore.; Northwestern University Medical School, Chicago, 1902; fellow of the American College of Surgeons; aged 58; on the staff of the Emanuel Hospital, where he died, October 12, of cerebral hemorrhage.

**Benjamin Franklin Lyon**, Lancaster, Texas; University of Tennessee Medical Department, Nashville, Tenn., 1892; formerly bank president; aged 73; died, October 17, in the Dallas Medical and Surgical Clinic Hospital, Dallas, of bronchopneumonia.

**James Houston Lamb** ☉ Paragould, Ark.; Hospital College of Medicine, Louisville, Ky., 1905; past president of the Greene County Medical Society; member of the school board; aged 59; died, September 21, of carcinoma of the liver.

**Edward Perry Clark**, Los Angeles; Hahnemann Medical College and Hospital of Philadelphia, 1897; member of the California Medical Association; served during the World War; aged 64; died, September 5, of coronary disease.

**Robert Blackburn Love**, Livingston, Texas; Medical Department of Tulane University of Louisiana, New Orleans, 1900; member of the State Medical Association of Texas; aged 63; died in October of ruptured peptic ulcer.

**Charles Pender Edwards**, Asheville, N. C.; Tennessee Medical College, Knoxville, 1900; served during the World War; aged 63; died, October 6, in the Morton F. Plant Hospital, Clearwater, Fla., of cerebral hemorrhage.

**Richard S. Bradley**, Dalton, Ga.; Southern Medical College, Atlanta, 1884; member of the Medical Association of Georgia; aged 80; died, October 19, of acute dilatation of the heart and fractured neck of the femur due to a fall.

**Chester C. Copelan** \* Springfield, Ill.; Chicago College of Medicine and Surgery, 1915; served during the World War; aged 47; on the staff of St. John's Hospital, where he died, October 9, of splenic myelogenous leukemia.

**Fisher F. Demuth**, Cecil, Ohio; Eclectic Medical Institute, Cincinnati, 1882; formerly member of the state legislature; past president of the Paulding County Medical Society; aged 82; died, October 16, of cerebral thrombosis.

**Conrad William Marxer** \* Indianapolis; Central College of Physicians and Surgeons, Indianapolis, 1897; served during the World War; aged 66; died, October 15, in the Methodist Hospital of carcinoma of the sigmoid.

**Herman John Wickman**, Riverside, Calif.; State University of Iowa College of Medicine, Iowa City, 1906; member of the California Medical Association; aged 60; died, September 29, in the Riverside Community Hospital.

**Charles G. Quammen**, Mantorville, Minn.; Keokuk Medical College, College of Physicians and Surgeons, 1903; aged 64; died, September 11, at Rochester of typhoid and perforation of an ulcer of the ileum with peritonitis.

**Edward W. Wahl**, Los Angeles; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1890; served during the World War; aged 71; died, September 3, in a local hospital.

**William Wallace Winans**, Rochester, N. Y.; Hahnemann Medical College and Hospital, Philadelphia, 1899; aged 64; on the staff of the Highland Hospital, where he died, September 24, of coronary thrombosis.

**Howard Andrew Lingenfelter**, Durango, Colo.; University and Bellevue Hospital Medical College, New York, 1899; member of the Colorado State Medical Society; aged 66; died, October 23, of heart disease.

**Earl Reuben Lee**, Denver; Temple University School of Medicine, Philadelphia, 1932; member of the Colorado State Medical Society; aged 33; died, October 9, in the Fitzsimons Hospital of adenocarcinoma.

**Claud E. Chandler**, Mukilteo, Wash.; Willamette University Medical Department, Salem, Ore., 1908; member of the Washington State Medical Association; aged 55; died, October 12, in a hospital at Everett.

**Louis Herbert Maxson**, Seattle; University of Pennsylvania School of Medicine, Philadelphia, 1910; member of the American Society of Anesthetists; aged 55; died, October 3, in the Providence Hospital.

**Alfred B. Wright**, Buffalo; University of Buffalo School of Medicine, 1901; member of the Medical Society of the State of New York; aged 60; died, September 24, of cerebral hemorrhage and hypertension.

**Edward Marcelis Clark**, Mamaroneck, N. Y.; Bellevue Hospital Medical College, New York, 1885; member of the Medical Society of the State of New York; health officer; aged 76; died, September 10.

**Walter P. Hailey**, Haileyville, Okla.; Missouri Medical College, St. Louis, 1899; aged 62; died, September 12, in the Albert Pike Hospital, McAlester, of calcification of the pineal gland and angina pectoris.

**Frederick Victor Lyman**, Velva, N. D.; University of Minnesota College of Medicine and Surgery, Minneapolis, 1903; aged 59; died, October 29, in a hospital at Minot of cerebral hemorrhage.

**William Elmer Boyer**, Newark, Ohio; Starling Medical College, Columbus, 1897; member of the Ohio State Medical Association; aged 68; died, October 4, of nephritis and Parkinson's disease.

**Graham Lawrence**, Shelbyville, Ky.; University of Louisville Medical Department, 1892; member of the Kentucky State Medical Association; aged 68; died, October 7, of cardiac thrombosis.

**Alois J. Blickhan**, Quincy, Ill.; Keokuk (Iowa) Medical College, 1891; member of the Illinois State Medical Society; aged 74; died, October 20, of arteriosclerosis and hypostatic pneumonia.

**Frederick Richmond McBrien**, Niagara Falls, N. Y.; Trinity Medical College, Toronto, Ont., Canada, 1891; aged 69; died, September 23, of uremia, pulmonary edema and nephritis.

**Edward Hardaway Manson Parham**, Lordsburg, N. M.; Medical Department of Tulane University of Louisiana, New Orleans, 1898; aged 61; died, September 10, of organic heart disease.

**Frank Heywood Stocker**, West Hartford, Conn.; New York Homeopathic Medical College and Hospital, 1897; aged 62; died, October 9, at the Hartford Hospital of lobar pneumonia.

**James Roy Bierly** \* Peoria, Ill.; Chicago College of Medicine and Surgery, 1911; served during the World War; aged 55; on the staff of the Proctor Hospital, where he died, October 18.

**E. C. McComas**, Flat Top, W. Va.; Tennessee Medical College, Knoxville, 1901; Maryland Medical College, Baltimore, 1904; aged 63; died, October 18, of acute dilatation of the heart.

**Lealon Edward Lamb** \* Clinton, Okla.; University of Oklahoma School of Medicine, Oklahoma City, 1928; aged 37; died, October 7, in the Menorah Hospital, Kansas City, Mo.

**John Charles Stewart**, Philadelphia; Hahnemann Medical College of Philadelphia, 1903; aged 54; died, September 16, of asphyxiation due to pressure from a deformity of the spine.

**James Joseph P. Armstrong** \* Douglas, Ariz.; Trinity Medical College, Toronto, Ont., Canada, 1893; aged 67; died, September 30, in La Jolla, Calif., of cerebral hemorrhage.

**Alson David Ferris**, Hardwick, Vt.; University of Vermont College of Medicine, Burlington, 1905; aged 71; on the staff of the Hardwick Hospital, where he died, October 5.

**George R. Clayton Jr.** \* La Fayette, Ind.; Illinois Medical College, Chicago, 1909; served during the World War; aged 54; died, October 17, of acute coronary thrombosis.

**Elliott Vanveltner Converse**, Palestine, Texas; Rush Medical College, Chicago, 1902; on the staff of the Missouri Pacific Lines Hospital; aged 59; died, October 8.

**Henry Walter Lilly**, Fayetteville, N. C.; Bellevue Hospital Medical College, New York, 1879; for many years bank president; aged 82; died, October 11, of myocarditis.

**Wilson R. Cushing**, Dublin, Va.; University of Maryland School of Medicine, Baltimore, 1881; member of the Medical Society of Virginia; aged 81; died, October 6.

**Seth Marion Angle**, Jackson, Mich.; Detroit College of Medicine, 1906; aged 64; died, October 4, in the W. A. Foote Memorial Hospital of intestinal obstruction.

**Oshea Stowell Brigham** \* Toledo, Ohio; Long Island College Hospital, Brooklyn, 1876; aged 86; died, October 16, of chronic myocarditis and acute bronchitis.

**Otto Kothe** \* Callicoon, N. Y.; University and Bellevue Hospital Medical College, New York, 1899; served during the World War; aged 61; died, September 27.

**William B. Marks**, Augusta, Ga.; University of Georgia Medical Department, Augusta, 1883; aged 76; died, October 11, of hypertension and coronary occlusion.

**William H. Barkley**, Cold Spring, Ind.; Cincinnati College of Medicine and Surgery, 1887; aged 82; died, October 24, of mitral stenosis and chronic prostatitis.

**John B. Mahan**, Cincinnati; University of Louisville (Ky.) Medical Department, 1889; aged 78; died in October of arteriosclerosis and cerebral hemorrhage.

**Thomas Edmund Fitzgerald**, Brooklyn; Cornell University Medical College, New York, 1904; died, September 10, in Cortland, N. Y.

**Thomas D. Tharpe**, Portsmouth, Va. (licensed in Virginia in 1908); aged 72; died, September 29, of coronary thrombosis.

**Ernest McNeill**, New York; Bellevue Hospital Medical College, New York, 1895; aged 66; died, September 6.

**J. E. Sutton**, Viola, Ark. (licensed in Arkansas in 1903); aged 69; died, September 21, of myocarditis.

**Willis A. Clark**, Cumby, Texas (licensed in Texas, under the Act of 1907); died, September 13.

## Bureau of Investigation

### LYDIA E. PINKHAM'S VEGETABLE COMPOUND GETS ANOTHER NEW DRESS

The carton labels of "Lydia E. Pinkham's Vegetable Compound" have been modified many times as a result of the activities of the Food and Drugs Act of 1906 as amended, and subsequent citations in connection with its enforcement. The cuts (below) showing the labels which have appeared since 1900 are not new to the readers of THE JOURNAL. In an article by Dr. Arthur J. Cramp in *Hygeia* for November 1935 concerning this preparation, it was stated:

"It will be noted in the oldest label reproduced at the time that fraudulent statements on the trade package were merely immoral instead of illegal and potentially expensive—that Lydia Pinkham's Vegetable Compound was claiming to be 'A Sure Cure for Prolapsus Uteri or

Falling of the Womb, and All Female Weaknesses,' listing a number of interesting, if intimate, conditions. Following the passage of the law, the line on the label reading 'A Sure Cure for' was deleted, and the information that the law required, giving the amount of alcohol present (at that time 18 per cent), was declared. The label still implied, however, that the Pinkham preparation was a cure for falling of the womb and many other serious conditions. It was on the basis of these claims that the Food and Drug officials proceeded against the Pinkham concern, and this action brought the verdict . . . [guilty of false and fraudulent labeling].

"Following this there was another change in the label, in which the stuff was 'Recommended for the Treatment of Non-Surgical Cases of Weaknesses and Disorders of the Female Generative Organs, Catarrhal Leucorrhoea and Irritation.' About this time, also, the alcohol content was changed from 18 to 15 per cent. A little later the statement relative to 'Catarrhal Leucorrhoea and Irritation' was deleted and yet another new label was issued. Then finally came the label that is being used today, in which it is stated that Lydia E. Pinkham's Vegetable Compound is 'Recommended as a Vegetable Tonic in Conditions for Which This Preparation is Adapted.' This statement is about as informative as it would be to say that 'For Those Who Like This Sort of Thing, This Is the Sort of Thing That Those People Like.'"

Now, according to an advertisement in the *American Druggist* for November 1938, the preparation has another new label. While it is still "Recommended as a Vegetable Tonic in Conditions for Which This Preparation is Adapted," if any, it is now called "Lydia E. Pinkham's Vegetable Compound (With Vitamin B<sub>1</sub>)"—200 International Units to the Daily Dose. Just why this particular vitamin was selected by these old-timers in the "patent medicine" business is difficult to know.

Lydia E. Pinkham, of course, never heard of vitamin B<sub>1</sub>. According to the Council on Pharmacy and Chemistry, vitamin B<sub>1</sub> is useful in correcting and preventing beriberi and anorexia of dietary origin in certain cases, and of value in securing optimal growth of infants and children, and is conceded to be a dietary essential which is of value in some conditions where difficulty in utilizing ordinary foods in the usual way is encountered. Since beriberi is only infrequently seen in the United States, and since the Pinkham preparation is obviously not for infants and children, it may be concluded that vitamin B<sub>1</sub> is added for correcting and preventing anorexia or to improve the utilization of ordinary foods where that utilization is not taking place. In view of many of the claims which have been used for the Pinkham preparation in the past, it is indeed surprising that the manufacturers, after deciding to add a vitamin, did not select vitamin E, since the latter vitamin, although not established, has been endowed with certain effects which were claimed for Lydia E. Pinkham's Vegetable Compound. How-

ever, there is no reason why the selection of the vitamin to be added to a nostrum of this type should be made on a rational basis.

The addition of vitamin B<sub>1</sub> to this old remedy is reminiscent of the change that was made in another nostrum many years ago. Quoting from THE JOURNAL for Sept. 28, 1912, it is stated in reference to "Peruna" that:

"In 1906 the Peruna company was notified that it either must put some medicine in its 'booze' or it could be sold only in saloons or other places carrying liquor licenses. The company thus found itself between the devil and the deep blue sea. If it left its nostrum as it was, it could only be sold by one who held a retail liquor dealer's license; this, of course, would at once make its real character evident to the purchaser. If, on the other hand, appreciable quantities of drugs were put into the stuff, it would spoil its sale as a beverage. Evidently believing that the preparation was so popular that nothing could hurt its sale materially, the company chose the latter course. A laxative was added and Peruna was still permitted to be sold as a medicine."

Peruna at that time contained about 20 per cent of alcohol. In 1920, however, this was reduced to 12 per cent, but in 1927 it was increased to 18 per cent and the senna was removed.

Changing formulas of "patent medicines" sold under the same name not infrequently causes considerable trouble to the user. Heavy users of Peruna probably did not appreciate its senna content. It must be granted, however, that there is probably nothing harmful in the addition of vitamin B<sub>1</sub> to Lydia Pinkham's Vegetable Compound. That there is any need for vitamin B<sub>1</sub> beyond that obtained in the normal diet, in any significant number of patients who take this "Compound," is something that is entirely unknown. It would be interesting to see exactly what type of claim is made by the manufacturer for this additional

ingredient. One is not able to determine this from the labels, since, as pointed out, the preparation is recommended in conditions for which it is adapted.

A current advertisement (cut above) may or may not refer in part or in toto to the new ingredient. Judging by this advertisement, vitamin B<sub>1</sub> may have been added for "tonic" effects, but a tablespoonful of the preparation, which has the alcoholic content of ordinary wine, may bring about certain "stepping-up" effects without the addition of any vitamin.

Another day, another label, a new age, a new ingredient, but still essentially the same old "female weakness" nostrum. Grandma used it and her daughter tolerated it, but her granddaughter should know better.

## Correspondence

### USELESS DUPLICATION IN TUBERCULOSIS WORK

To the Editor:—There is no other country in which there is more than one national tuberculosis association to combat tuberculosis in all its aspects and working in harmony with local societies, committees and specialistic organizations. Our country alone has the questionable distinction of having a number of so-called national bodies working and meeting independently of the National Tuberculosis Association. They include the American Clinical and Climatological Association, which meets annually and publishes its own transactions; the American Sanatorium Association, which meets at the same time as the National Tuberculosis Association and publishes its transactions with the latter's annual report; the Federation of American Sanatoria, which meets annually, and the American College of Chest Physicians and the American Academy of Tuberculosis Physicians, which meet also annually but like the former, independently of the meeting of the National Tuberculosis Association. The last three associations have for their official organ the monthly journal called *Diseases of the Chest*.

Before me is a letter dated Aug. 12, 1938, signed by the outgoing president, Ezra Bridge, and the incoming president, Bruce H. Douglas, of the American Sanatorium Association. In it there is first a suggestion for enlarged activities and members are asked to express their ideas concerning disbanding or enlarging and renaming the association. The letter concludes with the statement that the problem is now one of reorganization or amalgamation with the American College of Chest Physicians and the Academy of Tuberculosis Physicians. The Federation of American Sanatoria is not mentioned. The need of such a federation alongside the American Sanatorium Association, which has done such good work, is not apparent.

Why cannot all these activities be conducted under the auspices of the National Tuberculosis Association? The latter has a division for clinical section, administrative section, a pathologic section, a social work section, and so on. Nearly all phases of the tuberculosis problem except, perhaps, that of thoracic surgery are covered. This phase of phthisical therapy is so vast that there may be justification for the existence of an American Association for Thoracic Surgery, meeting separately and having its own monthly publications. Aside from that, one would think that the National Tuberculosis Association meets all the demands for considering in its program of work a complete tuberculosis therapy and prevention. Yet complaints have arisen: First, that the National Tuberculosis Association has neglected the western section of the country and particularly the interest of private sanatoriums; that the official organ of the society, the *American Review of Tuberculosis*, is too exclusive and inadequate to meet the demand for publication of many important papers on tuberculosis; that there is no criterion to judge competent specialists, and that the general practitioner has difficulty in selecting consultants when consultation is needed.

To obviate the latter condition, a number of tuberculosis physicians in the western and some eastern parts of the country united to form the American College of Chest Physicians and the American Academy of Tuberculosis Physicians and create for their official organ a monthly journal entitled *Diseases of the Chest* and publish a directory of experienced pneumothorax physicians.

If all men treating a particular part of the body should unite under the name of an academy, would it not lead to confusion, particularly in large cities, where there is usually one good academy with sections for all specialties? How bewildering would such multiplicity of academies be to the general practitioner. In tuberculosis of the lung there are already two, and a large number of good specialists do not belong to either. Heretofore the general practitioner has seemingly had little difficulty in choosing the consultant in whom he had sufficient confidence. Yet, in view of the importance of having for the young general practitioner starting out in practice an authentic guide to consult when consultation in tuberculosis is needed, I venture to quote from the letter already mentioned as one aim of the American Sanatorium Association the following: "To encourage qualified members of the organization to apply for registration with the American Board of Internal Medicine of the American Medical Association, to further the establishment by the American Medical Association of special examination, certification and registration of specialists in tuberculosis under the auspices of the American Board of Internal Medicine." This is a splendid way to clarify and solve the problem. The only suggestion I would make here is to add that the qualified member should be an expert in pneumothorax and application of pneumolysis. This would do away with the need of the directory for pneumothorax specialists. A list of consultants officially certified at the disposal of the general practitioner would be a guaranty of the competence of the consultant. While I have not the slightest doubt that the men who are members of the American College of Chest Physicians and the American Academy of Tuberculosis Physicians are equally competent as those who would pass the special examination qualifying as specialists in tuberculosis before the Board of Internal Medicine, membership in the two organizations created as a guaranty of qualification may not seem quite as secure to the young practitioner as the official list which the American Medical Association has at the disposal of inquirers.

The marvelous success in the reduction of the morbidity and mortality of tuberculosis was obtained prior to the past three years in which criticism, discontent and dissension among the workers arose. How great the result might be from united action of all the tuberculosis workers under the leadership of the officers and the Board of Directors of the National Tuberculosis Association, particularly since aided in their efforts by a benevolent United States government, the American Medical Association, the many state and local health departments, the equally numerous city and town tuberculosis associations and committees, the tuberculosis work of life insurance companies and, last but not least, all supported by an enlightened and generous public.

How very considerable a factor the United States government has already played in the antituberculosis crusade may be evident by a brief enumeration of its hospitals and sanatoriums. According to the latest Sanatorium Directory, the Veterans Administration Facilities for the care of the tuberculous ex-soldiers has no less than twenty-seven well equipped sanatoriums and all general hospitals operated by the administration have, besides, a few beds for observation and terminal cases. The U. S. Army and the U. S. Navy each has three tuberculosis hospitals; the U. S. Public Health Service operates seventeen tuberculosis hospitals and in addition to these there are six other U. S. Public Health Service hospitals which admit cases for observation and emergency care. For our Indians, our generous government has no less than fifteen sanatoriums

and thirteen general hospitals where tuberculous Indians are also admitted. Added to these government institutions the state, municipal and private sanatoriums throughout the country, we may proudly claim to have no less than 749 sanatoriums, preventoriums and general tuberculosis hospitals with a total capacity of 92,786 beds. In paying the just tribute to the splendid activities of our government, it is with equal pride that I state that no other body of civilian tuberculosis workers has achieved more success, has done more yeoman work in dealing with tuberculosis as a disease of the masses and to a very large degree is responsible for the marvelous mortality reduction of this disease than the National Tuberculosis Association.

The association elects a president every year and has a permanent secretary and treasurer. Hon. Franklin D. Roosevelt, President of the United States, is one of the association's honorary presidents. It has a board of directors of 101 which I would like to see increased by two representative physicians of the Negro race. Tuberculosis is still the medicosocial disease of the masses, attacking rich and poor alike, and among the colored population it is unfortunately most prevalent and with a seriously large morbidity and mortality. Much has been done and much is known but there is more to do and more to know.

In conclusion, I refer once more to that important letter addressed to all members of the American Sanatorium Association, which concludes as follows: "There is no doubt amalgamation of medical organizations in the tuberculosis field is desirable and that one organization of physicians interested directly and indirectly in tuberculosis should be the aim of all concerned."

S. ADOLPHUS KNOPF, M.D., New York.

16 West Ninety-Fifth Street.

## Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

### TESTING ENDOCRINE FUNCTIONING

*To the Editor:*—I should like to know about tests similar to the basal metabolic rate which indicate the normal or abnormal functioning of the endocrine glands, that is tests which determine normal or abnormal content of the various hormones of the pituitary, ovary and so on in such conditions as acne and menstrual disorders.

SOLOMON GREENBERG, M.D., Bayonne, N. J.

**ANSWER.**—The functional state of the endocrine glands can be determined in part by the following methods:

1. The amount of gonadotropic hormone in the blood and urine at the time of ovulation gives an estimate of the gonadotropic activity of the pituitary gland.
2. For the parathyroids by the fasting level of calcium and phosphorus in the blood.
3. For the pancreas by the fasting blood sugar content of the blood and by sugar tolerance tests.
4. The estrogenic content of the blood and urine during the menstrual cycle may give some indication of ovarian function. The chemical determination of urinary pregnandiol will reflect the activity of the corpus luteum.
5. For the testes by the amount of androgenic substance in the urine. In making these tests one can use any of the current methods described in any modern textbook of endocrinology (Werner, Lowenberg).

There is no pathognomonic hormonal picture associated with acne. Acne, however, is commonest at about the age of puberty. The condition is sometimes improved by the use of pituitary-like gonadotropic hormone extracts.

In all menstrual disorders it is advisable to eliminate non-endocrine factors such as debilitating diseases, blood dyscrasias and voluntary starvation for the purpose of reduction in weight. It is also important to eliminate organic lesions such as adrenocortical adenomas and pituitary adenomas.

In the absence of a nonendocrine factor or organic lesion of the endocrine glands, it is important to determine, if possible, which of the several endocrine glands is primarily responsible for the menstrual disorder. The thyroid function should be tested by means of the basal metabolism estimation and blood cholesterol.

A primary hypogonadism is determined by body measurements (relatively long extremities) and general appearance of the patient (boyish figure, usually underweight).

(a) The administration of gonadotropic substance is more effective in retarded puberty of boys with undeveloped sex organs.

(b) The postmenstrual state is characterized by the diminution or absence of estrogen and by an excess of the follicle stimulating hormone of the pituitary. Troublesome symptoms may be relieved by the prolonged administration of moderate doses of estrogen. This constitutes replacement therapy.

(c) Amenorrhea, secondary in character, if not caused by non-endocrine conditions or organic lesions of the pituitary, thyroid, adrenals or ovaries, may be overcome occasionally with low dosage irradiation of the pituitary gland and ovaries. When the uterus is hypoplastic, as it usually is in cases of amenorrhea, the administration of estrogen in large doses given intermittently is, sometimes, advisable for its stimulative effect on the muellerian tract.

(d) Menorrhagia may be controlled sometimes in those of child-bearing age by the administration of gonadotropic substance. In women at the menopause, menorrhagia may require a diagnostic curettage and the administration of radium. Progestin may be tried. It is usually ineffective.

It should be realized that the field of endocrine treatments in menstrual disorders is still largely in the stage of clinical investigation. Most menstrual disorders are best handled through the advice of a competent gynecologist.

### PANCREATIC EXTRACT IN URETERAL STONE

*To the Editor:*—What results have there been from the use of pancreatic extract in the treatment of ureteral stones?

ROBERT S. MCCENEY, M.D., Laurel, Md.

**ANSWER.**—The efficacy of pancreatic tissue extract in the treatment of ureteral calculi remains in the experimental stage. The extract, which is the residual solution after insulin has been precipitated from pancreatic tissue, was first found to possess definite vasodilator properties. According to the opinion of most investigators (Frey: *München. med. Wchschr.* 76:1951, 1929; Gley: *Presse méd.* 27:1279 [Oct.] 1929) the active agent is a hormone which is elaborated by and stored in the pancreas, passes into the blood in an inactive form, and is excreted in an active state in the urine. The so-called Frey hormone (Frey: *Ztschr. f. Biol.* 84:321, 1926) is a substance which has been isolated from urine and has properties identical with those of pancreatic extract; in pancreatectomized animals the rate of urinary excretion of this hormone has been found to be reduced 80 per cent. Whether the hormone exerts its dilatory effect by neutralizing epinephrine or by balancing an overstimulation of the sympathetic remains a moot point. Villaret (*Presse méd.* 37:633 [May] 1929), on the other hand, considers the physiologic activity of the extract due to sufficient amounts of choline, peptone and histamine which the hormone contains.

Because of its definite vasodilatory effects, Lazarus (*Urol. & Cutan. Rev.* 40:847 [Dec.] 1936) studied the efficacy of the extract in cases of impassable ureteral calculi. He reports concerning its use in eight cases of impacted ureteral calculi and two cases of ureteral stricture with associated spasm. In all cases save one he was easily able to pass dilating catheters and bougies to the renal pelvis thirty minutes after one or two 1.5 cc. injections of the extract. While Lazarus administered the extract intramuscularly, it is noteworthy that Elliot (*J. Pharmacol. & Exper. Therap.* 43:463 [Nov.] 1931) in animal experimentation found the extract to be active only when given intravenously and without effect when administered subcutaneously or intramuscularly.

Carrol (*South. M. J.* 31:233 [March] 1938) advises a dosage of from 2 to 4 cc. given intramuscularly; he reports pain at the site of injection as a constant finding, but it lasts only a short time. Generalized reactions to the drug are minimal and those reported consist merely of faintness and vertigo. The extract has been found to be effective in the treatment of renal colic due to stone, in postcystoscopic colic, in the instrumental removal of calculi in the lower ureter, and finally in the treatments for dilation of organic ureteral stricture. Carrol states that the extract produces prompt relaxation of the ureters and has borne this out by experimental hydrophorographic tracings of the normal human ureter under influence of the drug.

## CANCER OF BREAST

*To the Editor.*—A white woman aged 38 had a mass in the left breast removed. On biopsy and microscopic examination the mass was shown to be a highly malignant tumefaction composed of a cellular diffuse growth. The cells were unequal in size and shape; the nuclei were hyperchromatic and showed a large number of mitoses. The cytoplasm of the cells was either colorless or acidophilic. These cells were arranged in masses and columns and had a palisade formation. The desmoplastic reaction was reduced to but a few strands of connective tissue. In the center of some of these cells were areas of mucoid degeneration. The diagnosis was duct carcinoma of the breast (grade 3, moderately radio-sensitive). Should the entire breast be removed if no glands are present? Should radiation therapy be instituted before mastectomy? Would endocrine therapy aid the patient? What extension of life can be expected in this type of case? What is the prognosis? The x-ray report of the chest has not been received yet. The general physical condition and nutrition of the patient are good. The ears, nose, throat, heart, lungs, abdomen and extremities are normal. The blood pressure is 120 systolic, 80 diastolic. The blood count is within normal limits. The hemoglobin is 70 per cent, the red blood cell count 4,000,000. The patient has had three pregnancies going to full term and three miscarriages at two months. The blood Wassermann reaction is negative. The urine is normal. The mass was noticed in February 1938. After traumatic injury to the left breast the patient was operated on in August. The total mass measured 6.5 by 4.5 by 4 cm., covered by adipose tissue, and on cut section the mass was rather soft, was yellowish white, and had many chalky white pinpoints.

M.D., New York.

**ANSWER.**—It is evident from the record that the patient has a carcinoma of the breast. As she was operated on in August it is likely that further extension has occurred, as the tumor was removed locally even if there were no palpable nodes in the axilla. In about half the examples of carcinoma of the breast some involvement of the nodes is present, even though they are not palpable on physical examination. There is not the slightest advantage in preoperative irradiation, because any amount of radiation which can be given without serious damage to the healthy tissues will kill only a moderate percentage of the cancer cells and during the course of such preoperative irradiation further extension of the tumor into the breast tissues and the nodes is continuously taking place. A complete radical mastectomy should therefore be done immediately. After the wound is healed postoperative irradiation can be given. This increases the number of five year cures by about 10 per cent, provided the neoplasm has not already extended to the supraclavicular or mediastinal nodes; such a case is hopeless under any form of treatment. There is no evidence that any form of irradiation will completely sterilize diffuse carcinoma in the breast or in the axillary nodes; hence radical surgery at the present time is the only effective therapy of mammary carcinoma. This can be done with a cautery knife, electric spark or scalpel. There is some evidence that in advanced cases the use of the cautery or the cutting spark is preferable to scalpel surgery. In early carcinomas the scalpel method is just as effective as the others.

Endocrine therapy is useless. Prognosis is not possible in any individual case.

## OBSCURE ATTACKS OF VERTIGO

*To the Editor.*—During the last two years I have seen six cases almost exactly alike. I have seen three of these six during the last month. Vertigo of rather sudden onset accompanied by nausea and vomiting is the only symptom. It is so severe that the patients fall down. Bed rest and sedation halt the nausea and vomiting but have little effect on the vertigo. In each case physical examination has failed to reveal any hint as to the cause. No disturbance in hearing was present and no abnormality of the external ear or ear drum could be found. The highest blood pressure in the group was 130 systolic; 80 diastolic. No obvious focal infection was demonstrable and no history of previous medication or illness was obtained. The duration of the disease varied from five to twelve days and no recurrences have been seen. I have been unable to arrive at a diagnosis other than labyrinthitis and since I am in general practice in a small town I am unable to account for the frequency of these cases. Any information on this point as well as a better diagnosis, etiology and treatment will be appreciated. Two females aged 11 and 50, and four males aged 9, 38, 40 and 60 were affected.

FORD F. KEPPEN, M.D., Three Oaks, Mich.

**ANSWER.**—Since all the patients recovered after a brief illness and there were no recurrences, the more serious organic lesions are obviously ruled out and the disturbance must be assigned to the vestibular system, including either the labyrinth or the vestibular branch of the eighth nerve. Many toxic substances and conditions, notably tobacco, alcohol, uremia and intestinal absorption, cause vertigo, partially at least through the effect on the labyrinth, so it is logical to assume that bacterial toxins can also produce a labyrinthitis. This is seen in encephalitis, in which, however, there may be neuritis as well as direct toxic action.

Israel S. Wechsler (*A Text-Book of Clinical Neurology*, ed. 2, Philadelphia, W. B. Saunders Company, 1931, p. 276)

describes Gerlier's disease, an obscure condition in which vertigo is one of the principal symptoms. It is a rare disease occurring in certain areas of Europe as well as northern Japan, appearing only in the summer months, affecting mainly robust persons, coming in attacks which are repeated for a time and ultimately disappearing without recurrences. There are, however, usually ocular symptoms and muscular impairment.

The inquirer's description would fit certain prolonged migraine states were it not that they are single attacks. It therefore can probably be classed as a Ménière syndrome resulting from toxic labyrinthitis. In such attacks vertigo may be so severe that the patient clings to the side of the bed to remain in it or occasionally reports complete revolution of the bed or room.

Examination for nystagmus would be valuable and information as to the side to which the patients fall. Rotation tests, if suitable apparatus is available, would also be helpful.

## RECURRENT STOMATITIS

*To the Editor.*—A male about 18 years of age has stomatitis caused by yeast hyphae—*Leptotrichia buccalis*. The canker sores occur in the tongue, and on the inside of the cheek and lips. They clear up for a time and then recur. He has had this condition for a long time. I have tried bismuth preparations, arsphenamine and silver nitrate without avail. Could you suggest some treatment which might be effective?

HAROLD F. HULBERT, M.D., Dansville, N. Y.

**ANSWER.**—Since the stomatitis has resisted local therapy and has repeatedly occurred after treatment, it would seem best to look for and correct an underlying condition. It is quite possible that the yeast organism is a saprophyte existing only because of a local decreased resistance.

It would be well to be sure that the Wassermann reaction is negative and that a pulmonary involvement does not exist in conjunction with the stomatitis.

Occasionally a change in the amount of gastric acidity will clear the mouth of local lesions. Test the fasting gastric contents for the degree of free acidity. If a hyperacidity or hypoauidity is present, give an appropriate alkali or acid in the usual form to counteract the abnormality.

If this simple therapy fails, obtain cultures of the dominant organisms in the stool and make a cutaneous test, using these antigens as well as one prepared from the mouth culture. Desensitization to the organisms producing positive cutaneous reactions may result in a changed susceptibility and healing of lesions in the gastrointestinal tract.

Other mouth washes than those named can be used, such as aqueous solutions of thymol (1 to 1,000) or solution of hydrogen peroxide from 1 to 4 per cent, which are sometimes effective.

## TORTICOLLIS

*To the Editor.*—A Negro aged 44 complained that he "couldn't keep his face turned in front." He said that this condition had prevailed for four months. Examination showed that his chin stayed on the deltoid muscle of his left shoulder. He can turn his head and face forward only by using his hands. On removal of his hands it will snap back to the original position. There is one point of relaxation: when he drinks water, his head will stay quiet. The Wassermann reaction is negative; there is no deviation of the tongue, and eye convergence is normal. The patient neither smokes nor partakes of alcoholic beverages. All infected teeth have been removed. He gives evidence of perfect health otherwise. He has been receiving scopolamine hydrobromide one one-hundredth grain (0.00065 Gm.) for the last month triweekly. Please suggest treatment and references on this subject.

M.D., Missouri.

**ANSWER.**—The patient has a condition resembling a tonic torticollis or tic in which not only the right sternocleidomastoid muscle is at fault but the trapezius, splenius, scaleni and deep cervical muscles participate. Nearly all such cases are functional; that is, are not due to organic disease. They occur in persons who have a neuropathic diathesis. The fact that the patient's head will stay quiet when he drinks water indicates that there is no interference with function. There should be a complete neurologic examination to rule out any organic disease of the brain, spinal cord or cervical roots. If an organic lesion is present, one may do one of the operations described for that condition. Inquiry should be made in detail into the past history of the patient as well as with regard to the onset of the difficulty, because if a cause can be discovered the treatment must be directed to its removal. If no cause can be found, the following is suggested: Exercises in front of a mirror for five to ten minutes twice daily, the patient balancing a glass of water on top of his head; faradic current to the neck muscles on the left side of the patient once daily; supporting apparatus in the form of a pasteboard collar or a brace to be worn only in the daytime. Oppenheim's *Textbook of Nervous Diseases*, volume 2, is recommended for reference (pages 1246 to 1254).

## DANGERS FROM PYRENE FIRE EXTINGUISHERS

*To the Editor:*—A pyrene fire extinguisher was used May 17 to put out a fire in a narrow hall in which the ventilation was poor. The fire was caused by a paperhanger's gasoline steamer, which was used to steam off the paper on the wall. The steamer caught fire and caused a blaze in an area measuring 3 by 4 feet. About a quart of pyrene was used. Immediately afterward my patient had difficult breathing, became cyanotic and had gastrointestinal disturbances such as flatulence and inability to digest food. These symptoms became worse about the tenth day. Cyanosis, labored respiration, flatulence, indigestion and a rapid pulse, 120, were noticed as well as a strong taste of pyrene. An area of about 4 cm. around the patient's anus was red and inflamed. Supportive treatments such as digitalis, glyceryl trinitrate and strychnine were used with liquid and soft diet. Aromatic spirit of ammonia was used for the difficult respiration, this proving the most satisfactory stimulant. Four weeks later the patient noticed that the maxillary and ethmoid cells were blocked. When these were opened and drainage established, a taste and smell of pyrene were again noticed with a recurrence of symptoms. They subsided and the patient felt better. July 12 he took some sodium phosphate for constipation and again had a recurrence of symptoms, especially the difficult breathing, which is most noticeable at night. A roentgenogram was taken of the chest. The heart is normal in size; there is some infiltration about the hili of the lungs but this has been present for years. Now the patient's pulse is normal but he still has some difficulty in breathing at night and some cyanosis. What effect would pyrene mixed with gasoline have on the organs and structures of the body? What chemistry is involved in this condition? What change if any should be instituted in the therapy? G. J. SEARLE, M.D., Mansfield, Ohio.

**ANSWER.**—It appears probable that under the influence of heat the carbon tetrachloride of the pyrene was in part decomposed into phosgene. As little as 4 parts of phosgene per million of air may be injurious. The reason for the greater toxicity of phosgene over hydrochloric acid is probably that phosgene is absorbed as such and the toxic effects are relatively slight in the upper air passages where there is little moisture. The effect reaches its maximum in the alveoli, where the moisture content is much higher and the liberated hydrochloric acid causes corrosion. This probably explains the greater toxicity of phosgene as compared with comparable amounts of hydrochloric acid. Ordinarily phosgene action is delayed for a few hours but it may appear immediately. Its chief action leads to pulmonary edema and cyanosis. Ordinarily these manifestations are associated with a sense of constriction of the chest, coughing, nausea and vomiting. Pneumonia may appear and occasionally lung abscesses. Few patients die if they survive the first three days and escape serious sequels.

In the present instance the development of the sinusitis is undoubtedly on an infectious basis. At this late time there is no treatment with reference to the specific cause. At the outset of this type of case the patient should be placed absolutely at rest and given oxygen inhalation, and external heat should be applied. The use of digitalis as was administered in this case is commendable. The irritating cough should be diminished through the use of usual types of respiratory sedatives.

In this accident there is little reason to believe that any combination took place between escaping gasoline and carbon tetrachloride. Recurring taste of pyrene is believed to be unimportant, as little if any of this substance is retained in the nasal cavities. This type of accident is prone to provoke neuroses, but in this instance they should be dispelled through the knowledge that there is reasonable assurance that complete recovery will take place and within a short period. See also *Queries and Minor Notes* in *THE JOURNAL*, July 30, 1938, page 469.

## HYPERTONIC DEXTROSE SOLUTION IN PULMONARY EDEMA

*To the Editor:*—At this hospital it is almost a routine practice to administer hypertonic dextrose (50 cc. of 50 per cent solution) intravenously in the treatment of acute pulmonary edema and of right heart failure. No one has thus far been able to give me a satisfactory physiologic explanation for its use, nor have I been particularly impressed clinically by its results either alone or in conjunction with other methods. Is there a rationale behind this treatment or am I right in asserting that it is actually deleterious in that it throws an additional burden on an already overloaded circulation? M.D., New York.

**ANSWER.**—The administration of hypertonic dextrose solution intravenously in pulmonary edema and in failure of the right side of the heart is of certain value in some cases. The hypertonic solution takes up water from the tissues and may take enough fluid from the lungs to cause a symptomatic improvement. With normal kidney function and normal volume of blood flow through the kidneys the fluid taken up is excreted promptly and there is no increase in blood volume provided it is not given too rapidly. In cases of impaired kidney function it is always possible that there may be an increase in blood volume and that the increased blood volume might force an additional load on the heart. The additional dextrose content

is supposed to be of value to the heart muscle, although under ordinary conditions it is probable that sufficient dextrose is being supplied normally.

As in the case of other therapeutic procedures which are effective, the administration of a hypertonic solution of dextrose may do harm as well as good and the indications and contraindications for its use must be carefully weighed in each individual case. When the edema is paroxysmal and due to a temporary coronary insufficiency, for example, it may be of value. In coronary occlusion with an infarcted heart muscle the increased blood volume might do harm.

## X-RAYS CONTRAINDICATED FOR CARCINOMA OF LIVER

*To the Editor:*—A man aged 52 had five successive typical stone in the common duct gallbladder attacks the first week in August 1938 preceded by two weeks of progressive jaundice. September 8 a primary adenocarcinoma of the gallbladder and its duct with metastases to the surface of the right lobe of the liver was revealed at operation; the metastatic liver area was about 3 by 4 inches. Freeing of some two adhesions from the gallbladder duct produced a flow of bile with decided decrease in itching and an increase in appetite, but it is doubtful whether it will last. Could high voltage roentgen therapy be used here with advantage, offsetting the possible liver damage? Further operative procedures are, of course, out of the question, even drainage of the gallbladder which was so far below and back that a drain would kink. Is there any specific for the itching in severe jaundice? I have tried about everything but would appreciate any suggestions. Do you know of any two or three "appetizers" for carcinoma patients? One other complaint is that everything tastes sweet, even the water. M.D., Ill.

**ANSWER.**—Roentgen therapy is of no value in the treatment of either cancer of the gallbladder or cancer of the liver. This procedure is definitely contraindicated in the treatment of cancer of the liver. There are no specific therapeutic agents for the relief of itching in severe jaundice. There are no appetizers which are specially useful for carcinoma patients.

## UNUNITED FRACTURE AND SYPHILIS

*To the Editor:*—An unmarried white man aged 28 consulted me six months ago for treatment of a recently fractured toe (metatarsal bone). The toe was slow to heal and even now the fracture line is still clearly seen transversely through the middle third of the bone. Some callus is naturally present but calcification is not complete. The delayed union led me to suspect latent syphilis. The patient admitted that in 1935 he had three rather painless lesions on the penis for which he sought medical advice. He was sent to a laboratory for smears which he believes were reported negative; nevertheless he was given nine "shots" of an intravenous preparation but no more thereafter and no other treatment. A Wassermann test made recently was negative. Because he complained of visual disturbance he was referred to an ophthalmologist, who noted an inequality in the size of the pupils, which reacted slowly to light; a choroiditis was reported. On receiving this report I made a spinal puncture and found the fluid clear and not under increased pressure. The cell count was from two to three cells with a slight trace of globulin. The Wassermann test was negative but the colloidal gold curve was 0003330000. What is your interpretation of these observations? Do you think antisyphilitic treatment is indicated? If so, would you recommend trypanamide in view of the eye examination? M.D., California.

**ANSWER.**—There is no clear relationship between ununited fracture and syphilis. The most recent detailed orthopedic studies indicate that syphilis is in relatively uncommon association with ununited fracture and that nonunion is much more often due to other causes. It is, however, undeniable that in a few instances syphilis may be concerned in the causation of non-union of fracture.

The history of penile sores in 1935 is only suggestive of the diagnosis of syphilis and is by no means certain. About 50 per cent of all penile sores are syphilitic; the other 50 per cent are not syphilitic in character. This particular patient was treated on suspicion for early syphilis without a definite dark field or serologic diagnosis, and it is by no means certain from the history given that the nine "shots" were actually treatment for syphilis or were some other type of medication.

The ophthalmologic abnormalities recently discovered are also not diagnostic of syphilis. The slight inequality of the size of the pupils and the sluggish light reaction may be found in normal persons. Choroiditis may of course occur as a result of many causes of which syphilis is only one.

The abnormal colloidal gold curve cannot be definitely interpreted in view of the fact that the spinal fluid was otherwise normal. The particular reading of the gold curve reported suggests that this may be laboratory error.

On the basis of the facts given, no conclusion can be reached as to whether the patient does or does not have syphilis. The desirability of treatment and the type of treatment, if any is to be given, could be determined only after competent syphilologic consultation.

## IDIOSYNCRASY TO ATROPINE EYE DROPS

To the Editor:—To a girl in good health I gave 2 grains (0.13 Gm.) of atropine sulfate in one-half ounce (15 cc.) of water. Directions were to drop one drop in each eye three times a day. Her eyes were crossing at times and I wanted to refract them. Two hours later she returned after using a drop in each eye. She was in a state of excitement with gripping in the abdomen, bowel movement, pain in the legs, temperature about 103 F., headache, and flushing of the skin over the entire body. This seemed like a typical poisoning. Is there any specific treatment? Would these symptoms occur if I used homatropine hydrobromide in her eyes for a refraction?

M.D., Texas.

ANSWER.—The solution of atropine sulfate used was somewhat less than 1 per cent, which is the usual strength employed to cause paralysis of the ciliary body preceding refraction. The patient used two drops, which contained about 0.001 Gm. of atropine sulfate. The condition following this instillation was typical of atropine poisoning.

Idiosyncrasy to atropine is frequent and small doses may produce distressing and alarming symptoms. The fatal dose is relatively large, so that, although poisoning from atropine is fairly frequent, deaths from atropine are quite rare. As little as 0.1 mg. ( $\frac{1}{1000}$  grain) may cause symptoms of atropine poisoning in susceptible persons. The smallest fatal dose is recorded as 130 mg. (2 grains), given by mouth.

Atropine poisoning may be treated by giving a solution of tannic acid or, lacking this, a strong infusion of tea leaves. *Pilocarpine hydrochloride* in 0.01 Gm. (one-sixth grain) doses may be tried. This is repeated if necessary until the mouth is moist. Small doses of morphine sulfate may be given cautiously for excitement; for depression, if present, caffeine may be given.

Homatropine hydrobromide in amounts that would be used for ciliary paralysis does not induce systemic poisoning nor is there the tendency to produce or aggravate a condition of glaucoma, since the paralysis is of so much briefer duration. Homatropine does not produce delirium or mental excitement.

## MENSTRUATION AND FOOD SPOILAGE

To the Editor:—It seems to be generally agreed in this locality that if women do canning, especially that part of canning concerned with the pickling of foods, while they are menstruating, the food will later spoil. I have been asked for an explanation for this phenomenon and, having never heard of it myself before, I could think of no logical reason. Is this simply an erroneous belief concerned with the old superstitions surrounding menstruation or is there actually truth in it? I would appreciate any information you might be able to furnish me either to confirm or deny this belief.

M.D., Ohio.

ANSWER.—The inquirer may be referred to the first chapter in "Menstruation and Its Disorders" by Novak or to the monumental work of Ploss "Das Weib."

As is well known, there have been and still are many superstitious and erroneous ideas concerning the menstruating woman and the menstrual flow. Among others is evidently the one that the menstruating woman or the menstrual flow will in some way spoil food. There is no scientific basis for such a belief, and so far as actual scientific study is concerned there is apparently none mentioned in the literature.

## DIABETES INSIPIDUS

To the Editor:—A girl about 18 years of age with diabetes insipidus has absolutely no complaints beyond frequency of urination, day and night, and her urgent desire for water. I have not been able to find any other trouble in either the physical or the laboratory examination. A roentgenogram of the sella turcica reveals no abnormality there. She responds to the injection of solution of posterior pituitary and also of pitressin. Before such treatment was instituted she found that she had to get up at night about twelve times, so that her rest and sleep were much disturbed. Now, while she has been under observation and taking either solution of posterior pituitary or pitressin once a day, she gets up about twice a night. Is it advisable to give the patient a hypodermic and allow her to administer pitressin to herself at home every night?

D. A. MacGREGOR, M.D., Wheeling, W. Va.

ANSWER.—A spinal puncture can sometimes be made in early cases of diabetes insipidus, primarily for diagnostic purposes but also because the occasional condition may be immediately and sometimes permanently relieved by the withdrawal of from 10 to 20 cc. of spinal fluid. The results of injection of solution of posterior pituitary are satisfactory in most cases, but such treatment has disadvantages. Disagreeable side effects are provoked, such as pallor, headache, palpitation and diarrhea. Also, the material is expensive, and if the services of a physician or nurse are required to give the frequent injections necessary the cost may be prohibitive. Patients with diabetes mellitus customarily are trained to inject themselves with insulin, and few accidents have resulted. Solution of posterior pituitary, how-

ever, like solution of epinephrine, because of local vasoconstrictor action, is less safe to place in the hands of laymen for subcutaneous use. Anaerobic bacteria, spores of tetanus and those of gas-forming organisms, if accidentally introduced beneath the skin in a region rendered ischemic by vasoconstriction, theoretically would be more dangerous, and in practice more accidental infection has occurred from injection of vasoconstricting substances than from insulin. These objections are avoided by the administration of dry, powdered substance of the posterior lobe intranasally (Smith, F. M.: Diabetes Insipidus, Treatment by Intranasal Insufflation of Posterior Lobe Pituitary Powder, THE JOURNAL [March 3] 1934, page 660), which in most cases, if repeated at sufficiently frequent intervals, is as effective as any other method of administration of pituitary.

## VASODILATORS AND HEADACHE

To the Editor:—A woman aged 56 has hypertension with evidence of coronary sclerosis. She has had persistent headaches since puberty, relieved only by hot showers directly on the head and by hot applications to the head. This headache is always aggravated by vasodilators, which have been prescribed for her from time to time. It seems that vasodilators do not exercise a selective action in this case. Since she is not a patient of mine, I do not know of any other facts. She has been treated for a long time without beneficial results. I should like to know about any similar cases and whether there is anything one might do to relieve the precordial pain without aggravating the headache and vice versa.

M.D., New York.

ANSWER.—It is not possible to be explicit with the data at hand. The effect of vasodilator drugs in causing headaches in normal persons is well known. The headache accompanying the administration of glycerol trinitrate is an example. Some cases of chronic headache might reasonably be supposed to be aggravated by such drugs. The consequent fall in blood pressure might also be a factor.

If the more rapidly acting nitrites cannot be used for the acute paroxysms of cardiac pain, the effect of spirituous liquors might be tried or strong black coffee.

For constant use between the attacks, one of the purine base diuretics might be tried, for example one of the theobromines. They produce a definite coronary vasodilator effect with minimal peripheral vasodilatation.

## IONTOPHORESIS

To the Editor:—Please give me information regarding the deposit of metals or metallic solutions in the skin by electrolysis. I am not referring to the deposit of such metals by the use of the needle but by the diffuse action of such metals. I should appreciate details of the amount of current necessary, the apparatus to be used, and so on.

M.D., California.

ANSWER.—It is doubtful whether metals can be transported across and deposited in tissues of appreciable thickness. Little more than surface deposits can be expected. There is considerable controversy on this matter in the voluminous literature, but proponents for iontophoresis have by no means presented solid, convincing evidence for the exaggerated claims which many of them make. For details of this method the inquirer is referred to the following:

Kovacs, Richard: Electrotherapy and Light Therapy, Philadelphia, Lea & Febiger, 1938.  
Hollander, A. R.: Physical Therapeutic Methods in Otolaryngology, St. Louis, C. V. Mosby Company, 1937.  
The Interrupted Low Frequency and the Constant Electric Current in Medicine, Report of the Council on Physical Therapy, THE JOURNAL, Oct. 31, 1936, p. 1469.

## LYMPHOSARCOMA

To the Editor:—I received the following report on a gland removed from the supraclavicular area. What is the prognosis and what is the best treatment for this condition? There are no metastases and the patient's general condition is excellent. This is of approximately two months' duration. Microscopic examination: The normal architecture of the lymph node is almost completely replaced by diffuse hyperplasia of atypical lymphoblasts. There are infiltrations of lymphoblasts through the capsule into the surrounding fat tissue. There are occasional eosinophils, but the absence of myeloid giant cells and fibroblasts would indicate lymphoblastoma rather than Hodgkin's disease.

M.D., Ohio.

ANSWER.—The treatment for lymphosarcoma is either by x-rays or by radium. The prognosis depends on the extent of the disease and the efficiency of the treatment. When adequate radiation therapy is administered to a localized area of lymphosarcoma there is an excellent chance of complete sterilization of the treated focus. The bad prognosis usually associated with this disease is due to the fact that there frequently exist outlying areas which are affected by the disease but which are clinically not recognizable.

## Medical Examinations and Licensure

### COMING EXAMINATIONS

#### STATE AND TERRITORIAL BOARDS

Examinations of state and territorial boards were published in THE JOURNAL, December 10, page 2235.

#### NATIONAL BOARD OF MEDICAL EXAMINERS

NATIONAL BOARD OF MEDICAL EXAMINERS: Parts I and II. Medical centers having five or more candidates desiring to take the examination, Feb. 13-15, May 1-2 (Part II only—limited to a few centers), June 19-21, and Sept. 11-13. Ex. Sec., Mr. Everett S. Elwood, 225 S. 15th Street, Philadelphia.

#### SPECIAL BOARDS

AMERICAN BOARD OF ANESTHESIOLOGY: An Affiliate of the American Board of Surgery. Written examination, Part I, will be held in various cities of the United States and Canada, April 8. Oral examinations for all candidates, St. Louis, May 13-14. Applications must be filed not later than sixty days prior to the date of the examinations. Sec., Dr. Paul M. Wood, 745 Fifth Ave., New York.

AMERICAN BOARD OF INTERNAL MEDICINE: Written examinations will be held in various parts of the United States, Feb. 20. Application must be received on or before Jan. 1. Sec., Dr. William S. Middleton, 1301 University Ave., Madison, Wis.

AMERICAN BOARD OF OBSTETRICS AND GYNECOLOGY: General oral, clinical and pathological examinations for all candidates, Part II examinations, (Groups A and B) will be held in St. Louis, May 15-16. Application for admission to Group A examinations must be on file in the Secretary's office by March 15. Sec., Dr. Paul Titus, 1015 Highland Bldg., Pittsburgh (6).

AMERICAN BOARD OF OPHTHALMOLOGY: St. Louis, May 15. Applications must be filed before February 15. Sec., Dr. John Green, 3720 Washington Blvd., St. Louis.

AMERICAN BOARD OF ORTHOPAEDIC SURGERY: Memphis, Tenn., Jan. 13-14. Sec., Dr. Fremont A. Chandler, 6 N. Michigan Ave., Chicago.

AMERICAN BOARD OF OTOLARYNGOLOGY: St. Louis, May 12-13 and Chicago, Oct. 6-7. Sec., Dr. W. P. Wherry, 1500 Medical Arts Bldg., Omaha.

AMERICAN BOARD OF PATHOLOGY: Richmond, Va., April 8-9. Sec., Dr. F. W. Hartman, Henry Ford Hospital, Detroit.

AMERICAN BOARD OF PEDIATRICS: New York, April 26. Appointments must be made before Dec. 26. St. Louis, May 16. Appointments must be made before Jan. 16. Cincinnati, Nov. 14-15. Appointments must be made before July 14. Sec., Dr. C. A. Aldrich, 723 Elm St., Winnetka, Ill.

AMERICAN BOARD OF PSYCHIATRY AND NEUROLOGY: New York, Dec. 28-30. Sec., Dr. Walter Freeman, 1028 Connecticut Ave. N.W., Washington, D. C.

AMERICAN BOARD OF RADIOLOGY: St. Louis, May 11-14. Sec., Dr. Byrl R. Kirklin, 102-110 Second Ave. S.W., Rochester, Minn.

AMERICAN BOARD OF UROLOGY: New York, Jan. 13-15. Sec., Dr. Gilbert J. Thomas, 1009 Nicollet Ave., Minneapolis.

### California July Examination

Dr. Charles B. Pinkham, secretary, California State Board of Medical Examiners, reports the written examination held at Los Angeles, July 12-14, 1938. The examination covered nine subjects and included ninety questions. An average of 75 per cent was required to pass. One hundred and twenty-eight candidates were examined, 120 of whom passed and eight failed. The following schools were represented:

School	PASSED	Year Grad.	Per Cent
College of Medical Evangelists.....(1935)	80.2, 81.4, 83.3, 75.6, 76.2, 78.2, 78.2, 78.2, 78.8, 79, 79.2, 79.2, 79.3, 79.6, 80, 80.6, 80.7, 80.9, 81.1, 81.3, 81.4, 82.1, 82.2, 82.8, 82.8, 83, 83, 83.1, 83.2, 83.3, 83.4, 83.6, 83.7, 83.8, 84.3, 84.3, 85.2, 85.6, 85.6, 86, 86.3, 87.7	(1935)	76.4,
Stanford University School of Medicine.....(1938)	85, 86.3, 86.3	(1938)	82.9,
University of California Medical School... (1937)	82.2, 84.7, 85.6, 85.8	(1937)	76.1,
University of Southern California School of Medicine... (1938)	78.2, 78.6, 79.7, 79.9, 83.3, 84.4, 84.4, 84.6, 84.7, 84.8, 84.9, 85.2, 85.6, 85.9, 86.3, 86.4, 86.8, 86.9, 87, 87.2, 87.6, 87.6, 87.8, 88.7, 89.2	(1938)	77.1,

### Indiana June Examination

Dr. J. W. Bowers, secretary, Indiana State Board of Medical Registration and Examination, reports the written examination held at Indianapolis, June 22-24, 1938. The examination covered fifteen subjects and included 100 questions. An average of 75 per cent was required to pass. One hundred and nine candidates were examined, 108 of whom passed and one failed. The following schools were represented:

School	PASSED	Year Grad.	Number Passed
Loyola University School of Medicine.....(1938, 2)*		(1938, 2)	2
Northwestern University Medical School.....(1938, 2)		(1938, 2)	2
Rush Medical College.....(1937), (1938)		(1937), (1938)	2
School of Med. of the Division of Biological Sciences.....(1937)		(1937)	1
University of Illinois College of Medicine.....(1938, 3)		(1938, 3)	3
Indiana University School of Medicine... (1937), (1938, 77)		(1937), (1938, 77)	78
Indiana University School of Medicine.....(1938, 2)		(1938, 2)	4†
University of Louisville School of Medicine.....(1938, 2)		(1938, 2)	2

Ludwig-Maximilians-Universität Medizinische Fakultät, München.....(1936)		(1936)	1
Universität Heidelberg Medizinische Fakultät.....(1914)		(1914)	1
Magyar Királyi Pázmány Petrus Tudományegyetem Orvosi Fakultasa, Budapest.....(1926)		(1926)	1

School	FAILED	Year Grad.	Number Failed
Rheinische Friedrich-Wilhelms-Universität Medizinische Fakultät, Bonn.....(1937)		(1937)	1

\* These applicants have completed the medical course and will receive the M.D. degree on completion of internship. Licenses have not been issued.

† These applicants will be granted licenses on presentation of diploma.

### Nevada Reciprocity Report

Dr. John E. Worden, secretary, Nevada State Board of Medical Examiners, reports three physicians licensed by reciprocity after an oral examination on Aug. 1, 1938. The following schools were represented:

School	LICENSED BY RECIPROCITY	Year Grad.	Reciprocity with
Kentucky School of Medicine.....(1902)		(1902)	Montana
University of Minnesota Medical School.....(1938)		(1938)	Minnesota
University of Buffalo School of Medicine.....(1918)		(1918)	New York

### New Mexico October Report

Dr. Le Grand Ward, secretary, New Mexico State Board of Medical Examiners, reports the written examination held at Santa Fe, Oct. 10-11, 1938. The examination covered thirteen subjects and included ninety questions. An average of 70 per cent was required to pass. One candidate was examined and passed. Fourteen physicians were licensed by endorsement from August 29 through November 3. The following schools were represented:

School	PASSED	Year Grad.	Per Cent
Rush Medical College.....(1937)		(1937)	90.3

School	LICENSED BY ENDORSEMENT	Year Grad.	Endorsement of
College of Medical.....(1916)		(1916)	California
University of Colorado.....(1934) N. B. M. Ex.		(1934)	N. B. M. Ex.

University of Wisconsin Medical School.....(1929)		(1929)	Wisconsin

## Book Notices

**The Heart in Pregnancy.** By Julius Jensen, Ph.D. (in Medicine), M.R.C.S., L.R.C.P., Assistant Professor of Clinical Medicine, Washington University School of Medicine, St. Louis. Cloth. Price, \$5.50. Pp. 371, with 5 illustrations. St. Louis: C. V. Mosby Company, 1938.

This volume represents a critical survey of the literature and present day thought on heart disease and its relation to problems of reproduction. Cardiac disease is probably the most frequent accidental complication of pregnancy and accounts for about 7 per cent of maternal deaths. Improved antepartum care has greatly reduced the death rate. The improved prognosis for the patient with cardiac disease during pregnancy has been made possible by cooperative study and care of the patient by a competent internist and an obstetrician. The author, who is an internist, has had the exceptional opportunity of studying a large group of patients with cardiac disease in cooperation with the obstetrician of a prominent American clinic. The first few chapters of this book are devoted to a discussion of the physiology of the heart and circulation in their relation to menstruation, pregnancy and labor. The various cardiac complications are thoroughly discussed. The management of a patient with heart disease in pregnancy and labor is considered. One can take little exception to these general considerations. Some of the rare conditions, such as congenital heart disease and bacterial endocarditis, are accorded more space than their rare occurrence deserves, but there is so little information concerning these conditions in textbooks and periodicals that these thorough discussions are highly desirable. In the author's discussion of the interruption of pregnancy for cardiac disease, he says that "it should now rarely be performed, for either a woman should not undertake pregnancy or she should be capable of carrying it through." This summarizes the value of preconceptional examination for the prospective mother. The volume represents a diligent survey of more than 1,000 references. A great amount of statistical data is thoroughly analyzed. These, plus the experiences of the author, provide an excellent outline of the heart in pregnancy. The work is a real contribution and can be heartily recommended to the obstetrician and the student of the problems of human reproduction.

**Digrafía: Nuevo método radiográfico para el estudio de los órganos móviles.** Por Guido Pollitzer. Paper. Pp. 104, with 41 illustrations. Buenos Aires: Imprenta amorrotu, 1937.

The author recognizes that probably the best method generally available for the study of the movement of organs is fluoroscopy, but even the most carefully made notes and the most tenacious visual memory will not permit comparisons of observations at different times. Stereoscopy does not serve the purpose. Radiocinematography is too expensive, both for the initial outlay for apparatus and for maintenance. Radiokymography has its disadvantages and is more expensive than the simple apparatus required for the author's method. A roentgenkymogram is a roentgenogram of an organ in movement obtained during a prolonged exposure. The "digram" (the author's term) is the production of instantaneous roentgenograms of an organ "surprised" in different positions. The roentgenkymogram registers all the movement, while the "digram" registers only the predetermined positions. The roentgenkymogram in spite of all these considerations gives a blurred image except on its borders, while the "digram" gives a clear image. The roentgenkymogram permits observations of only a small part of the detail of the image of the organ. The "digram" shows 50 per cent or at least one third of the organ. The "digram" is obtained by a frame superimposed on a cassette. In the frame is a grid having bars 3 mm. wide, separated by spaces exactly 3 mm. wide. Thus half the film is exposed when the grid is in one position. The grid is then changed and the half previously exposed is now covered and the other half now uncovered is exposed. A special viewing box permits one to see alternately the first and the second exposures at a slow or rapid rate, as may be desired. This method of viewing gives the illusion of a cinematographic record of movement. As a matter of fact, it is comparable to the commonly seen advertising signs where by a series of parallel shutters one may see first one sign and then another as the turning of the multiple parallel shutters alternately shows the

one or the other. The "digraph" does not compete at all with the roentgenkymograph. It serves another purpose. The roentgenkymograph has had its chief value in recording the amplitude of the movements of the heart and in similar somewhat related studies, whereas the "digraph" will have considerable usefulness in recording and graphically reproducing such lesions as pleuro-pericardial adhesions, adhesions of the diaphragm, chest or the mediastinum, such as accompany nonopaque foreign bodies in the bronchus. The apparatus is not yet made in the United States but it should not be very expensive.

**Chronic Intestinal Toxemia and Its Treatment with Special Reference to Colonic Therapy.** By James W. Wiltzie, A.B., M.D., Consultant in Physical Therapy at the Binghamton City Hospital, Binghamton, N. Y. Cloth. Price, \$3. Pp. 268, with 8 illustrations. Baltimore: William Wood & Company, 1938.

This is an earnest plea for the greater use of colonic irrigations. It is written by a physician who evidently is intelligent, earnest and thoroughly convinced of the value of the method. He starts out with somewhat of an inferiority complex, realizing fully that the medical profession has little faith in his hobby. It has no faith because it has been trying the method at intervals ever since the pyramids were built, and after each flare-up of favor it has watched the idea of intestinal intoxication die down again.

Today the principal users of the method are laymen, cultists and out-and-out charlatans. Obviously, any physician who hopes to overcome this handicap and convince the profession that it should again start washing colons must bring forward a large mass of well documented information. He must show that he is well educated, logical and thoroughly scientific in his presentation and weighing of evidence. His published case reports must show much clinical good sense, and perhaps most important of all, if he is going to convince unbelievers, he must face squarely and explain away all the evidence which they might bring against him. Side-stepping and sneering will not help.

Although this is probably the best written argument for the theory of chronic intestinal toxemia that has yet appeared, it still falls far short of being convincing and satisfying. Although there is much that seems scientific and clinically sound, there is also much that seems like pseudoscience.

One of the most curious features of the book is the author's insistence that the benefits of colonic lavage do not result from the emptying of the bowel but from some remarkable effect in "promoting tubular and cellular drainage, the healing of diseased tissues, the restoration of normal colon function, the improvement of both capillary and lymphatic circulation, and of liver function. The principle back of free drainage is that infection tends to disappear when drainage is adequate, and in the absence of a feeder."

It is startling also to find the use of enemas strongly deprecated as a most pernicious habit which under no circumstances should be started. According to Wiltzie the use of enemas by the patient himself actually tends to undo all the beneficial work that is accomplished by the colon washer in his office. Under such circumstances one should expect to find an exact and detailed explanation of the differences between an enema and an irrigation, but this we have not been able to find in the book.

One thing that will tend much to discourage the scientifically trained physician is the refusal of the author to face the large array of facts which are not favorable to his theory. These are hardly mentioned and, like most enthusiasts, the writer is inclined to quote only that scripture which is to his purpose. The well known fact that in many cases the symptoms of supposed autointoxication are produced reflexly by a distention of the rectum (as shown by the fact that relief comes immediately after defecation) is dismissed rather contemptuously.

It appears then that, although the book will be an excellent text for those who believe in colonic irrigations, it is not sufficiently convincing to induce a trained clinician or gastroenterologist to put a special table into his office and to start off trying to cure all sorts of diseases with this method.

Incidentally, one of the worst defects of the book is that the reader is left with doubts as to what are the indications for the use of this method. At least we are left with the idea that the essential point is to treat the patient with colonic washings, and then if he gets better, one can conclude that he was suffer-

ing from colonic toxemia. The physician who is at all philosophical and logical in his thinking always distrusts this type of argument, if only because with it one can go far to prove that faith healing and spine cracking are excellent modes of healing.

*Die natürliche Heilweise im Rahmen der Gesamtmedizin. Eine Vortragsreihe, veranstaltet von der Berliner Akademie für ärztliche Fortbildung, Berlin NW 7, Robert-Koch-Platz 7. Herausgegeben von Professor Dr. Curt Adam, Leiter der Berliner Akademie für ärztliche Fortbildung. Paper. Price, 14 marks. Pp. 354, with 43 illustrations. Jena: Gustav Fischer, 1938.*

This collection of postgraduate lectures for physicians is symptomatic of modern Germany. Its avowed purpose is that underlying the "new German healing art": the aim to secure a synthesis of scientific medicine with "folk medicine," even though scientific medicine is, after all, the daughter of "folk medicine." It has happened here, as it does in families, that the daughter has lost the appreciation of the wisdom of the mother, while the latter does not understand her daughter any more. It is the sick who suffer therefor, especially those patients for whom the "nature remedies" are prescribed. There is nothing radically different, however, in this series of addresses by various lecturers from the trends of pre-Nazi Germany in the extolling of the value of physical and dietetic remedies: an emphasis that, in this country, which has a tendency to neglect these therapeutic measures, is even more needed than it is in Germany. Unfortunately, the "synthesis" to be effected is with "homeopathy" and most especially "nature cure" empiricism without subjecting these to the strictures of scientific weighing and measuring and to emphasize the "immeasurable" as justification for doing this.

*Injection Treatment of Varicose Veins and Hemorrhoids. By H. O. McPheeters, M.D., F.A.C.S., Attending Physician, New Ashbury, Fairview and Northwestern Hospitals, Minneapolis, Minn., and James Kerr Anderson, M.D., F.A.C.S., Instructor in Surgery, University of Minnesota School of Medicine, Minneapolis. Cloth. Price, \$4.50. Pp. 315, with 82 illustrations. Philadelphia: F. A. Davis Company, 1938.*

This well written compact volume represents an authoritative and practical treatise. It is remarkably complete and yet brief enough to appeal to the busy practitioner. The chapters on anatomy and embryology as well as the other sections on the theoretical considerations of these subjects are excellent. The treatment of varicose veins and the complicating varicose ulcers is described in clear language based on the actual large experience of the authors. All the latest developments are considered and explained in simple language. Considering the voluminous literature that has appeared in recent years and the many controversial points in theory and technic that have been advanced, it is a relief to read a clear exposition which makes available a practical technic based on the best modern conceptions of these subjects. The section on the treatment of hemorrhoids by the injection method, which has been written by Dr. Anderson, is likewise noteworthy for its brevity and condensation into a practical monograph of the voluminous literature on this small but important subject to the general practitioner. The volume represents a type of medical textbook which is too infrequently published, a compact yet detailed practical handbook written in simple direct language containing the best of the latest in the treatment of varicose veins and hemorrhoids.

*Neue biometrische Untersuchungen von Spermien und Fertilität. Von Dr. med. et phil. Konstantin D. J. Generales, jun. Paper. Price, 7 marks. Pp. 84, with 17 illustrations. Stuttgart: Ferdinand Enke, 1938.*

It is now well recognized that in the clinical study of sterility in mated pairs of human beings a thorough examination of the male partner's semen is obligatory, and particularly a study of the morphologic and physiologic characteristics of the spermatozoa. There is also a growing recognition of the fact that detailed investigation of the individual germ cells may possibly be illuminating in cases of genetically grounded diseases and defects. This book is a useful contribution to the methodology of this field of inquiry. In addition to detailed instructions regarding the fixing, staining and measuring of sperm samples, elementary biometric techniques are explained and exemplified. The author's own studies of individual variation in spermatozoa embodied in this book are based on the examination of more than 20,000 sperms. As strictly biometric indexes of quality (in the sense of fertilizing power) of spermatozoa, chief depen-

dence is placed on (a) the product of the coefficients of variation for length and breadth of the sperm head, (b) the coefficient of variation for the volume of the sperm head, which however is not directly measured but is a derivative function of head length and breadth, and (c) the relation between the coefficients of variation for sperm head length and breadth in respect of their absolute magnitudes (fertilizing power being alleged to be diminished when  $C_1 - C_2 > 1$ ). We incline to the view that most critical biometricians would be less trustful of the diagnostic indications derived from coefficients of variation than the author is. The mathematical structure of that constant has made most workers wary about putting too heavy a burden of interpretation on it. The book is clearly written and, even though probably not the final and definitive word on the subject, will certainly help toward its further scientific development.

*A Text-Book of X-Ray Diagnosis. By British Authors. Edited by S. Cochrane Shanks, M.D., Physician, with Charge of Out-Patients, Departments of Radiology and Electro-Therapy, Charing Cross Hospital, London, Peter Kerley, M.D., M.R.C.P., D.M.R.E., Physician to the X-Ray Department, Westminster Hospital, London, and E. W. Twining, M.R.C.S., L.R.C.P., D.M.R.E., Radiologist, Royal Infirmary, Manchester. In three volumes. Volumes I and II. Cloth. Price, 50s; 42s. Pp. 591, with 393 illustrations; 458, with 307 illustrations. London: H. K. Lewis & Co., Ltd., 1938.*

A comprehensive survey of the field of x-ray diagnosis sufficiently detailed for reference purposes and with an adequate bibliography has not been available heretofore in one publication in the English language. This work, projected in three volumes by a group of authoritative English radiologists and clinicians, attempts to fulfil this need. Although it does not measure up in all respects to its foreign language counterparts, the general plan is admirable. In each section are brief discussions of the normal anatomy, the pathology and the chief clinical features of the disease under consideration. This is followed by the roentgenologic features of the condition, occasional discussions of differential diagnosis and a reasonably adequate bibliography. X-ray technic is discussed only as it relates to strictly medical procedures. There is no general introduction to the subject of x-ray diagnosis, no effort at exposition of broad principles nor any other correlative material. The first volume contains a section on the cardiovascular system by Kerley which is only fairly well done. All the information is sound and it is easily read. The illustrations are too few and the subject is insufficiently detailed. X-ray examination of the peripheral vessels is also covered in this section. The second section, on the respiratory tract, by Twining, is excellent. The discussion of fluoroscopic technic and general principles underlying the examination of the lungs is particularly good. The author describes in some detail his simple method of tomography and its application to pulmonary diagnosis. The final section, on the urogenital tract, by Marshall and Shanks, is well presented.

The second volume contains a section on the alimentary canal by Shanks. Gastric ulcer and postoperative gastric conditions are both splendidly detailed. In other respects, however, this section is disappointing. There is little attention to differential diagnosis and the illustrations are clearly insufficient. No reproductions of esophageal varices, gastrojejunocolic fistula or bezoars of the stomach, to mention a few, are given. The section on the biliary tract, by Kerley, is well written with a sufficiency of detail. His account of the appearances in biliary dyskinesia is of particular interest. There is, in addition, in this volume a fairly good discussion of the abdomen, in general, by Shanks and an excellent section on the roentgenologic aspects of obstetrics and gynecology by Roberts and Wilson. The third volume, on the bones and joints and the nervous system, has not yet been published.

There is throughout a regrettable absence of any reference to accuracy or dependability of the x-ray examination. For example, in the detailed and otherwise satisfactory discussion of miliary tuberculosis there is no mention of the fact that weeks may occasionally pass before the roentgenologic aspects of this condition become apparent. It is strange to find so little reference to pneumoperitoneum, which is covered only in relation to gynecology. In the discussion on intestinal obstruction, an extremely important indication for roentgenographic study, the information is most inadequate. There is no reference whatever to retroperitoneal or paraduodenal hernia. American roentgenologists will certainly not agree that filling of the terminal

ileum during examination of the colon is an "undesirable accident." Aside from this, however, there are few statements to which exception can be taken. The bibliography is fairly good but is somewhat marred by glaring typographical errors, such as Schwick for Swick, Davies for Davis, and Chester for Stewart. It is almost incredible that the bibliography of a section on the stomach and duodenum should have omitted all reference to the work of Lewis Gregory Cole. The illustrations, less than 400 for each volume, are too few for a reference book. They are, with few exceptions, reproduced as positives. The printing and figuring are of satisfactory quality. The too few diagrams and elaborately labeled illustrations are excellent.

Despite many deficiencies, these volumes represent an important effort to correct a serious deficiency in our literature. The whole work will no doubt form an indispensable part of every roentgenologist's library and will prove of great value to all who need authoritative reference to the details of x-ray diagnosis.

**The Single Woman and Her Emotional Problems.** By Laura Hutton, B.A., M.R.C.S., L.R.C.P. With a foreword by David Forsyth, M.D., F.R.C.P. Second edition. Cloth. Price, \$1.50. Pp. 173. Baltimore: William Wood & Company, 1937.

This small volume, by an English woman physician, is written for laymen, more particularly for single women. It is a book, however, that can be read with profit by most physicians as well. The author briefly reviews the position of the single woman today. The problem of the single woman has become a more pressing one in countries involved in the World War, since the potential mates of many thousands of women were killed. The modern psychology, emanating chiefly from Sigmund Freud, that offers the basis on which the author discusses her thesis is skilfully if necessarily incompletely outlined. The psychologic problems of friendships among women, sexual problems and sexual inversion are dealt with. Dr. Hutton approaches her thesis not from the standpoint of psychopathology but rather as the problems ordinary women subjected to the special tensions and difficulties associated with a lonely or at least a manless existence are faced with. Her treatment of these problems is sympathetic, humane and scientifically sound. The book can well be read by most intelligent women who face the prospect of a life without marriage.

**Studien über die Entstehung und Entwicklung der Lungentuberkulose mit besonderer Berücksichtigung des Verlaufs der tuberkulösen Erstinfektion des Jugendlichen und Erwachsenen.** Von Hagvin Malmros und Erik Hedvall. Unter Mitwirkung der Röntgendiagnostischen Abteilung (Chefarzt: Dozent H. Hellmer) des Universitätskrankenhauses zu Lund. Nr. 68, Tuberkulose-Bibliothek, Beihefte zur Zeitschrift für Tuberkulose. Herausgegeben von Dr. Franz Redeker, Oberregierungs- u. Obermedizinalrat, Berlin, und Dr. Karl Diehl, dirigierender Arzt, Sommerfeld. Paper. Price, 27 marks. Pp. 223, with 140 illustrations. Leipzig: Johann Ambrosius Barth, 1938.

Periodic study with tuberculin test and x-ray examination of more than 3,000 young men and women at the University of Lund in southern Sweden permitted the authors to observe the development of pulmonary lesions in 133 students. Their observations dealing with the genesis of tuberculosis are of great importance. The studies were carried out with thoroughness and the results are reported in detail. Only rarely was the "subclavicular infiltrate" found to be the earliest lesion. As a rule the initial manifestation of pulmonary tuberculosis was above the clavicle, indicated by discrete soft spots in the x-ray film. Spread below the clavicle was usually followed by confluence of the spots, simulating a primary exudative infiltrate. Apical infiltrations of this sort were frequently noted, without evidence of a primary complex, in students who had only recently become tuberculin positive. Apical lesions progressed to clinical disease and occasionally to death, with equal frequency in students recently infected and in those long positive to tuberculin. The authors warn that apical or subapical lesions must be considered serious even when they are believed to be of first infection type. Illustrative roentgenograms, reproduced with remarkable clarity, greatly enhance the value of this report. The progression of tuberculosis from minute apical infiltrations to advanced disease can be plainly followed in these excellent reproductions. This volume will prove of exceptional value to physicians interested in the pathogenesis of tuberculosis and will be highly useful to roentgenologists, who will find it a comprehensive atlas of the early lesions of pulmonary tuberculosis.

**Practical Otolaryngology.** By Morris Levine, M.D., F.I.C.S., Clinical Professor of Otolaryngology, New York Post-Graduate Medical School, Columbia University, New York. Second edition. Cloth. Price, \$5.50. Pp. 416, with 149 illustrations. Philadelphia: Lea & Febiger, 1938.

This popular small book on diseases of the ear consists essentially of a compilation of lectures given by the author for the New York Post-Graduate Medical School of Columbia University. The book is short and concise, written in an easily readable style. There is not much detail or theory, which the author defends in his preface for reasons which appear good to him. Hence, though it is an excellent book for medical students, general practitioners and perhaps those starting the practice of otology, it is not complete enough for the practicing specialist. The descriptions of disease are good. The chapters on acute otitis media and mastoiditis are among the best in the book and are worthy of praise. There is an excellent chapter on petrositis which summarizes most of the new thought on this subject. If there is any criticism of the book it lies in the preliminary chapters. In spite of the fact that the author prefers not to consume too much space in the discussion of theories and debatable points, it does not seem altogether fitting that a book published in 1938 should omit those newer studies of otology pioneered by Wever, Bray and others, and which have given such impetus to theory and practice in recent years.

**Comparative Study of the Marmas.** By P. V. Krishna Rao, B.A., M.B., B.S., Professor of Physiology and Hygiene, Govt. Indian Medical School, Madras. Cloth. Price, 5s. Pp. 68, with illustrations. Madras: P. Varadachary & Co., 1937.

The word Marma is derived from the Sanskrit root "Mru," "Marane" and it applies to a place of vital importance in the body which, if injured, results in serious consequences or death sooner or later. Surgeons of ancient India laid down the rule that in a case of surgical operation the situation and the dimension of each local marma should first be studied well and the incision for operation made in such a way as to avoid even the edge of a marma. The knowledge of the marmas was made use of in ancient warfare and in hunting after wild animals by aiming at the marmas with the arrows. This science is also practiced in the art of wrestling in some parts of India and Japan. The author has extracted the relevant passages from Hindu Scriptures and translated them into English. He describes, in the light of modern anatomy, the structure of each "marma" with its corresponding anatomic parts, with their names according to the western system. The author then prescribes medicines and methods of treatment for disorders of each affected "marma." These are derived from his own private practice and not from any standard Hindu works. It is doubtful whether modern medicine would approve this part of the book. The "marmas" themselves are still authentic.

**Personal Hygiene.** Compiled by Robert Olesen, Assistant Surgeon General, United States Public Health Service. Supplement No. 137 to the Public Health Reports. U. S. Treasury Department, Public Health Service. Paper. Price, 10 cents. Pp. 46, with illustrations. Washington, D. C.: Supt. of Doc., Government Printing Office, 1938.

Health maintenance is largely a personal responsibility. This short compilation of information concerning personal hygiene, originally prepared for radio use, has been revised and brought down to date. Cleanliness, immunization against infectious diseases, school hygiene, food, posture, sport, care of the hair and scalp, and first aid are among the subjects briefly but clearly discussed. A short bibliography is appended. This booklet serves as a useful guide to a few of the phases of personal hygiene.

**A Manual of Tuberculosis for Nurses and Public Health Workers.** By E. Ashworth Underwood, M.A., B.Sc., M.D., Medical Officer of Health, County Borough of West Ham. With an Introduction by Professor J. R. Currie, M.A., M.D., F.R.C.P., Professor of Public Health in the University of Glasgow. Second edition. Cloth. Price, \$3.25. Pp. 401, with 53 illustrations. Baltimore: William Wood & Company, 1938.

For nurses on duty with tuberculous patients this book is excellent. The manner of infection and description of primary and secondary types are well handled. The description of symptoms, what produces them and what a nurse might do is carefully explained. Sanatorium care, together with an explanation of what is to be expected from such treatment, is given in detail. All a nurse should know about the surgery of all forms

of tuberculosis is set forth. From the point of view of the public health worker and preventive medicine the book is not all inclusive. This phase of tuberculosis is not presented in sufficient detail. Had the title omitted "public health workers" the work would accomplish its purpose.

Berättelse från styrelsen för cancerföreningen i Stockholm över verksamhetsåret 1937. Index of Papers Published at Radiumhemmet 1909-1937. Report on Cases Treated at Radiumhemmet 1921-1937. Paper. Pp. 103. Stockholm: K. L. Beckmans Boktryckeri, 1938.

The list of papers contains 287 titles. The tabular summary of the results of treatment covers 55,038 cases grouped under 879 different disease conditions. Any details of treatment are not given.

## Bureau of Legal Medicine and Legislation

### MEDICOLEGAL ABSTRACTS

**Workmen's Compensation Acts: Recovery Retarded by Mental Sequelae of Industrial Injury.**—Vallee had a spinal malformation and chronic bronchitis. In the course of his employment, April 3, 1936, four of his ribs were fractured, one rib piercing a lung. His employer paid him full compensation from April 3 to Oct. 12, 1936, and thereafter refused to pay him anything. In a proceeding instituted under the workmen's compensation act, the trial court awarded the workman compensation on the basis of total disability to April 3, 1938, and of partial disability from then to April 3, 1940. The employer thereupon brought exceptions to the Supreme Court of New Hampshire.

The employer's argument, said the court, is substantially fallacious in its insistence that the direct consequences of the accident are limited to the immediate consequences. Any aggravation of the claimant's spinal malformation or of the bronchitis, by the accident or the consequences thereof, was properly attributed to the accident. Furthermore, the mind, as well as the body, may be hurt by a traumatic injury. If conditions arising in the course of recovery affect the mind in such a way as to retard convalescence, the resulting prolongation of disability may be attributed to the accident. Loss of work and of bodily strength and activity may cause depression or melancholy which, even though mild, may prolong disability.

The defendant's medical expert testified that the plaintiff's condition was partly due to his injury, that some soreness from the broken ribs persisted and greatly worried him, and that he was suffering from "a mental condition to a large extent which started at the time of the accident." This mental condition, the witness testified, accounted for the workman's feelings of weakness and loss of strength whenever he tried to do any work. He further testified that the workman's complaints of backache were due to the long time he had been out of work, his apprehensions about himself, the long period of sitting around and disuse of his back muscles, so that they had become soft and weak. This evidence, the court said, together with that tending to show that before the accident the workman worked steadily while thereafter he was unable to work except to a negligible extent, that his general health was poor after the accident, that he lost 15 pounds in weight and became anemic, that he had severe back pains and that his complaints were not of pretended suffering, was sufficient to support the findings of the trial court. Although the workman's back was not hurt in the accident, the court thought it reasonable to infer that inactivity due to the accident brought about some condition in connection with his spinal deformity which caused suffering from it, and although his chronic bronchitis was progressive as time went on, it was a fair deduction that the accident developed and increased the speed of its progress.

After reviewing carefully the entire record, the Supreme Court was of the opinion that the award of compensation made by the trial court to the workman was justified.—*Tallice v. Spaulding Fibre Co. (N. H.)*, 197 A. 697.

**Optometry Practice Acts: Revocation of Optometrist's License Because of Corporate Employer's Use of Prohibited Advertising.**—The Minnesota optometry practice act authorizes the state board of optometry, after notice and hearing, to revoke the license of any licensee found guilty of conduct of a character likely to deceive or defraud the public, including such practices as price advertising, advertising free examinations, splitting fees or the use of untruthful, improbable, misleading or impossible statements in connection with practice or treatment. The act authorizes the board to make any rules and regulations, not inconsistent with law, which it may deem necessary for the effective enforcement of the act. The board undertook, by rule 6, to declare that unprofessional conduct would be imputed to a licensed optometrist employed by a firm or corporation if his employer engaged in any advertising prohibited by law or board rule. The plaintiff, a licensed optometrist, was charged, in a revocation proceedings, with being in the employ of a jewelry company that used types of prohibited advertising, that he, the plaintiff, aided and abetted his employer in doing so, and that he was therefore guilty of unprofessional conduct. The district court, Ramsey County, at the instance of the plaintiff, enjoined the board from revoking the plaintiff's license, and the board appealed to the Supreme Court of Minnesota.

In the opinion of the Supreme Court, the board was without power to revoke the plaintiff's license under the circumstances stated. Since the optometry practice act, said the court, provides that unlicensed persons may sell optometric articles if such sale is under the control and direction of a licensed optometrist who is in charge of and in personal attendance at the place where such articles are sold, clearly it is lawful for a licensed optometrist to accept such employment. The employment being lawful, it seemed to the court to be contrary to the letter and spirit of the law to hold the employee responsible for the employer's violation of the law and to impute knowledge of such violations to the employee. If the employer violates the act in any manner, he may be enjoined or prosecuted. There is no right or justice in punishing the servant for the misdeeds of the master. The court did not overlook the fact that the complaint filed with the board charged that the plaintiff aided and abetted his employer, but the court thought that it was clearly evident from a reading of the complaint as a whole that that allegation was a conclusion drawn from the fact that the plaintiff did not quit the employment when informed of the employer's transgressions.

The primary purpose of optometry legislation, continued the court, is the protection of human eyesight. Such legislation was not enacted to further the personal interests of the optometrists except so far as their advancement in skill and efficiency serves the primary purpose of the law. When the purchaser of eyeglasses has the services of a competent licensed optometrist in selecting and fitting them to his eyes, he has had all the benefits the law intended.

The Supreme Court accordingly affirmed the judgment of the trial court enjoining the board from revoking the plaintiff's license.—*Williams v. Mack (Minn.)*, 278 N. W. 585.

### COMING MEETINGS

- American Academy of Orthopedic Surgeons, Memphis, Tenn., Jan. 15-19.
- Dr. Carl E. Badgley, 1313 East Ann St., Ann Arbor, Mich., Secretary.
- American Association for the Study of Neoplastic Diseases, Baltimore, Dec. 28-30. Dr. Eugene R. Whitmore, 2139 Wyoming Avenue N.W., Washington, D. C., Secretary.
- American Student Health Association, New York, Dec. 29-30. Dr. Ruth E. Boynton, Students Health Service, University of Minnesota, Minneapolis, Secretary.
- Eastern Section, American Laryngological, Rhinological and Otological Society, Boston, Jan. 11. Dr. Frank E. Kittredge, Masonic Temple, Nashua, N. H., Chairman.
- Middle Section, American Laryngological, Rhinological and Otological Society, Sioux City, Iowa, Jan. 19-20. T. R. Gittins, Davidson Bldg., Sioux City, Iowa, Chairman.
- Southern Section, American Laryngological, Rhinological and Otological Society, New Orleans, Jan. 14. Dr. Francis E. LeJeune, Maison Blanche, New Orleans, Chairman.
- Western Section, American Laryngological, Rhinological and Otological Society, Spokane, Wash., Jan. 29. Dr. Frederic G. Sprowl, Medical Arts Bldg., Spokane, Wash., Chairman.

## Current Medical Literature

### AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1928 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (\*) are abstracted below.

Apparent Alteration of Tetanus Toxin Within Spinal Cord of Dogs. W. M. Firor and A. Lamont, Baltimore.—p. 941.

**Acute Cholecystitis.**—Of 167 patients with acute cholecystitis on whom Graham and Hoeft operated within forty-eight hours of the onset, death occurred in six. Cholecystectomy was the operation of choice in these cases, while cholecystostomy was reserved for the more critical ones. Certain factors make a cholecystectomy for acute cholecystitis more difficult than one performed in the quiescent period. The gallbladder is often tense and distended. The tissues are more friable and the bleeding is more profuse. There is more swelling around the cystic duct. It may be necessary to aspirate the gallbladder, and the authors usually prefer in these acute cases to remove it from above downward, controlling the bleeding from the liver bed by the pressure of a gauze pad and a retractor. An oozing liver bed that cannot be obliterated can be quickly peritonealized and rendered dry by a free omental graft lightly tacked in place by a few interrupted sutures. A large percentage of cultures taken during the first forty-eight hours remain sterile and therefore infection is not a major problem at this time. Acute cholecystitis is not like acute appendicitis and there is not the same necessity for prompt operative intervention. But of twenty-seven patients operated on within two to five days of onset two died and of twenty-two operated on five or more days after onset five died. It is seen that a delay of more than five days gives a high operative mortality and raises the question of whether operation should be performed or further delay advised.

This must be decided for each individual case. A lowering in mortality can be accomplished by education of the public and cooperation between the family physician and the surgeon to secure a prompt operation, early in the attack, for every person suffering from acute cholecystitis who is a good operative risk.

**Thymol Therapy in Actinomycosis.**—Joyce believes that the most effective treatment of actinomycosis is a combination of radical surgical intervention and thymol medication. His procedure is to give orally 1.5 Gm. of powdered thymol in capsules two out of every three days, to open the sinuses widely, to curet and fill them with thymol in olive oil (10 per cent solution) and then to inject the sinuses each day. Small strips of gauze are inserted to keep the sinuses open.

**Wound Healing.**—In an attempt to ascertain the exact value of topical agents in the treatment of infected wounds, Anderson measured precisely the changes in the size and bacterial count of twenty wounds. The wounds studied differed in size, etiology and bacterial flora, but each was of the type regarded as surgically infected. The majority of infected wounds, adequately drained and not containing sloughing tissue, in normal persons will heal according to a regular geometric curve, the rate being proportional to the size of the wound and decreasing with the age of the patient, regardless of the type of local treatment. Invasive organisms, extensive necrosis and the presence of dead tissue in the wound, even without active infection, retarded healing. The presence of a large number of organisms on the surface of wounds does not ordinarily retard healing. Local agents considered had little or no beneficial effect on the healing of infected wounds, except for the action of zinc peroxide in specific cases. The few antiseptic agents which had definite bactericidal action on surface organisms in normal granulating wounds were ineffective in the presence of tissue necrosis, and it is only under the latter circumstances that the existing infection is likely to retard healing. In the management of infected wounds, less attention should be given to the selection of a potent local antiseptic agent. It is of more importance to consider the problem of increasing local tissue immunity, which may be influenced by factors of a general nature remote from the site of the wound, and aiding the sequestration of necrotic tissues rich in bacteria by mechanical or chemical débridement and adequate surgical drainage.

Reading Difficulties in Children. G. E. Berner and Dorothy E. Berner, Philadelphia.—p. 829.  
Carbon Disulfide Poisoning. R. McDonald, Philadelphia.—p. 839.

**Panophthalmitis and Sympathetic Ophthalmia.**—Samuels points out that panophthalmitis is of relatively rare occurrence today, not only because severely injured eyes are excised before the infection is far advanced but because the usual infecting germs do not lead to a widespread purulence. However, in regions with warm climates it is still relatively frequent, whereas in the United States it probably represents not more than 2 or 3 per cent of all intra-ocular infections following injuries. Of 101 globes showing characteristic sympathetic tissue, reported in a previous paper, there were only three which had been affected with panophthalmitis. In this same series there were nine instances of typical sympathetic infiltration of the choroid without involvement of the fellow eye. Of these nine, seven followed common endophthalmitis and two followed panophthal-

mitis. Thus three cases of panophthalmitis in a series of 101 cases of sympathetic ophthalmia is not an insignificant figure and suggests that a panophthalmitic eye may not be so harmless as has been commonly thought.

**Infections of the Hand.**—Devenish states that during a period of three years 388 patients with infections or injury of the hand were seen at the University College Hospital. There were sixty-one cases of injury, leaving 327 cases of infection (whitlow), in 192 of which there was a history of injury. Of the cases of infection of the digital pulp, of paronychia and of subcutaneous abscess and cellulitis of the fingers, trauma occurred in 64, 50 and 65 per cent, respectively. With the other types of whitlow the figures were not large enough to indicate the significance of trauma. If trivial injury received prompt treatment, the incidence of whitlow was much reduced. Such measures are immediate cleansing of the wound, its protection against contamination and a warning to the patient to report immediately if the lesion becomes painful. At present so much attention is focused on the site of the incision and the necessity for early operation "to relieve tension" that unnecessary operations are apt to be encouraged. Premature incision for spreading cellulitis is by no means a harmless blunder; it may determine the onset of sloughing. It is more difficult to abort an infection of the pulp than to arrest cellulitis elsewhere in the hand, but this is probably due to the situation of the pulp at the end of the arterial tree of the upper limb. Premature incision for cellulitis of the pulp is thus more likely to result in extensive sloughing and may possibly cause necrosis of the terminal phalanx. Swelling and congestion of the inflamed area are reduced to a minimum by elevation of the limb and immobilization. Splinting for immobilization or elevation must not interfere with the circulation. The hand seems to be dependent for efficiency on constant use. Complete disuse, whether produced by therapeutic immobilization or by a tender scar, is followed by atrophic changes in the fingers, which result in their disablement. This may be prevented in the former instance by discontinuing immobilization and by starting active movements as soon as healing is established.

**Serum Therapy for Streptococcal Infections.**—Sheplar and her associates report sixty-six severe cases of streptococcal infection, seen in consultation, treated with concentrated anti-streptococcus serum. The youngest patient was 19 days old and the oldest 80 years. Of the sixty-six patients, eighteen died. There were six patients with diffuse bacterial meningitis and two with generalized peritonitis, types of disease in which the serum at present available does not offer much hope. In only three of the eighteen cases was the effect of the serum really

disappointing. Five successful cases are cited illustrating the use of the serum under varied conditions. The first is an example of temporary invasion of the blood stream from lesions on the hands, treated by subcutaneous injections of concentrated state serum to a total amount of 40,000 units. The patient recovered promptly from the infection. The second patient was desperately ill with streptococcal pneumonia, empyema and bacteremia. She was treated with polyvalent streptococcus serum from February 10 to April 2 and the total amount of serum used was 760 cc.; this treatment was augmented by multiple transfusions and surgical drainage of the pleural cavity. The third patient, with postoperative streptococcal infection, was treated with the regular (unconcentrated) serum of the New York state department of health. The first administration of the serum (25,000 units) on May 16 was followed by improvement. An injection of 5,000 units of the serum was given on May 20. After a period of improvement there were a relapse and extension of the inflammation and on May 29 more serum was given in divided doses, to a total amount of 15,000 units. This was followed by 10,000 units on May 30 and 5,000 units on each of three consecutive days. This time there was prompt improvement without further relapse. The fourth patient had postoperative streptococcal infection. A streptococcus bacteriophage was applied to the wounds and 40,000 units of concentrated streptococcus serum (New York state) was given intramuscularly on each of two days. The last patient was treated with sulfanilamide in moderate doses for four days and with streptococcus serum on these four days and for eight days thereafter. She made a rapid recovery. There was no incompatibility between the serum and sulfanilamide or streptococcus bacteriophage employed simultaneously. There is reason to believe that superior results may be obtained by the careful use of these agents in combination. The authors propose to designate as the Hugh Young reaction the chill, sudden rise in temperature, diaphoresis and fall in temperature so often observed in the treatment of sepsis when an adequate amount of the antibacterial agent has been introduced into the blood stream to initiate the eradication of the infecting bacteria.

**Maggot Therapy for Hematogenous Osteomyelitis.**—Maddock used maggot therapy in the treatment of twenty-nine cases (thirty-one lesions) of hematogenous osteomyelitis of the tibia. Most of the patients had been operated on by other surgeons, and treatment with maggots was begun after a period of antecedent treatment. The great advantage in the use of maggots seems to lie in the high percentage of closed lesions and in the relative scarcity of recurrences. This is doubtless due to the ability of the larvae to uncover hidden sequestrums and to seek out small abscesses which might otherwise become included in the new bone. Maggot therapy is not indicated in all cases of osteomyelitis. Only when the patient fails to make reasonable progress clinically is it necessary to consider the use of maggots. For chronic osteomyelitis their usefulness is probably much greater. After seven years of experience and many trials of various substitutes the author still feels that the condition can be treated profitably with maggots and that no lesion should be given up as hopeless until maggot therapy has been tried. Of the thirty-one lesions, twenty-six up to the time of writing were closed, one still required treatment, two had necessitated amputation and two patients were lost track of.

**Facial Paralysis Complicating Mastoid Operations.**—Sullivan bases his conclusions on his reparative operative experiences in sixty cases of facial nerve palsies and anatomic dissections of the temporal bones of animals. 1. The systematic identification of the sigmoid sinus plate, the horizontal canal, the digastric crest, traced forward to the posterior bony canal wall, and the joining together of the latter two structures reveals a plane for the position of the vertical segment. 2. The tympanic segment of the nerve may be injured in the simple mastoid operation. The position of the horizontal canal is fixed, the anterior margin of which is the posterior border of the fallopian aqueduct. Therefore this structure must constantly be observed in opening the mastoid antrum, as in reality it affords a protection to the nerve. 3. In the radical operation the tympanic segment must be visualized. The "bridge," so called, should never be removed by any manipulation directed from the middle ear toward the mastoid antrum. 4. The nerve in sclerotic bone is more superficial on the tympanic aspect of the posterior bony canal wall, the so-called pyramidomastoid segment, and is most prone to injury in the lowering of the hypotympanum and the removal of the bony margin of the annulus tympanicus on this surface. 5. Handled thus, facial paralysis complicating the mastoid operation is on the way toward coming under surgical control, the prognosis, heretofore invariably grave, will give better promise and the malady will be less and less common.

**Amyloidosis of Adrenals as Cause of Addison's Disease.**—Mendel and Saibil present a case of Addison's disease developing on the basis of amyloidosis in the course of pulmonary tuberculosis, with no evidence of tuberculosis in the adrenals, an apparently uncommon occurrence. The adrenals are frequently involved in the course of generalized amyloidosis, yet Addison's disease on this basis is extremely rare. It appears to depend on the degree of amyloid infiltration and the extent of clinical development of the syndrome of Addison's disease.

**Low Leukocyte Count in Pyogenic Infections.**—After determining the leukocyte and polymorphonuclear counts in cases of appendicitis, pneumonia and other pyogenic infections, Watson and Sarjeant believe that the sequence of events in leukocytosis is as follows: 1. During the early stages of a severe pyogenic infection there is a rapid production of leukocytes, which are delivered to the blood as young forms. This causes an increase in the total leukocyte count and a shift to the left in the polymorphonuclear count. 2. The white cell count continues to rise until, with the onset of suppuration, leukocytes are withdrawn from the blood to the infected focus more rapidly than they are poured into the blood from the bone marrow. If the infective process continues to spread, this withdrawal of leukocytes from the circulation may be of sufficient extent to produce leukopenia. The curves of the leukocyte and polymorphonuclear counts in uncomplicated cases of lobar pneumonia are similar to the curves

in uncomplicated cases of acute appendicitis, rising abruptly with the onset of the infection, remaining high during the acute stages of the disease and falling together to the base line as the infection subsides. In cases of lobar pneumonia complicated by empyema, the curves resemble those in acute appendicitis with abscess formation or peritonitis, as with the onset of suppuration in the pleural cavity the leukocyte count shows an abrupt fall while the polymorphonuclear factor remains elevated.

**Epidural Block.**—From an experience of 500 epidural block anesthetics Sword and Harrington conclude that the procedure can be used in most types of cases in which operation is below the diaphragm. Old age is not a contraindication. In the majority of cases adequate sedation can be produced by the proper timing of the preliminary medication. Too great a fall in blood pressure occurs if morphine, scopolamine or pentobarbital sodium is given in the usual doses an hour before the operation. The main objection to this type of anesthesia seems to be the delay it causes in a busy operating room. Poor surgical risks show a better recovery when this method of anesthesia is used.

Delayed Toxic Reaction to Sulfanilamide: Case Report. L. Danziger, Baltimore.—p. 340.

**Absorption and Excretion of Sulfanilamide.**—Marshall and his associates compared the absorption and excretion in dogs of moderately soluble sulfanilamide, easily soluble mono-ethanol sulfanilamide and slightly soluble disulfanilamide. They found that ethanol sulfanilamide is absorbed and also excreted very rapidly, while disulfanilamide is absorbed slowly and excreted rapidly in comparison with sulfanilamide. Little increased absorption occurs with a large dose of the easily insoluble compound as compared with a small one. Sulfanilamide when given in solution by mouth is absorbed much more quickly than when

given in solid form. Absorption is slight from the stomach but rapid from the intestine. Sulfanilamide derivatives do not all pass into the spinal fluid as readily as does sulfanilamide.

**Passage of Sulfanilamide Through Human Placenta.**—Speert studied the transmission of sulfanilamide through the human placenta. His studies confirm those of Lee, Anderson and Chen that the drug passes readily from mother to fetus. The sulfanilamide concentration of the fetal blood rapidly approaches that of the mother, equilibrium being reached within approximately five hours. This was true for both the free and the acetylated forms of the drug, a finding at variance with the results of the foregoing authors. The concentration of sulfanilamide in the amniotic fluid indicates a correspondingly free passage of the drug. Clinically, infants show no ill effects from the drug either at birth or during the neonatal period. The data presented represent the placental transmission of sulfanilamide in the human being only at term. It is entirely possible that in earlier stages of pregnancy great differences from the present observations may occur.

**Tuberculous Allergy Without Infection.**—On the basis of their studies Sabin and Joyner conclude that guinea pigs can be rendered hypersensitive to tuberculo-protein by small, repeated, intradermal injections of active tuberculo-protein. The addition of tuberculophosphatide to the protein speeds up the process of sensitization and enhances it so that the reactions become indurated and necrotic, closely simulating those of the disease. Active tuberculo-proteins induce a new formation of monocytes and some epithelioid cells. The addition of phosphatide to the protein brings about a massive formation of epithelioid cells. The increase in the speed and intensity of the sensitization may be correlated with the increased cellular reaction to the mixed injections. The intradermal route is the best for these sensitizations, probably because it provides the greatest dose per cell of the sensitizing agent. The degree of sensitization artificially obtainable by the synergistic action of tuberculophosphatide and tuberculo-protein is quite comparable to the degree of sen-

sitization naturally occurring in tuberculous animals; moreover, this degree of sensitization may be induced with amounts of the materials from the bacilli which could conceivably be present in the tissues of an infected host.

**Eastern Equine Encephalomyelitis.**—King studied the neuropathologic features of equine encephalomyelitis in the guinea pig. The histogenesis of the disease process is described. After peripheral inoculation the earliest detectable pathologic change is the accumulation of leukocytes within the lumen of the blood vessels and the proliferation of the vascular adventitia. This precedes the appearance of any significant perivascular cuffing and may or may not be accompanied by a few polymorphonuclear leukocytes. The typical lesion is a fairly well circumscribed focus of polymorphonuclear leukocytes accompanying the foregoing vascular changes. The leukocytes may be numerous or sparse and may or may not be accompanied by neuron destruction. The neocortices and olfactory cortices are the principal sites of predilection. A distinction between inflammatory and degenerative lesions depends on the relationship between the neuron destruction and the exudative changes. After intracerebral inoculation the inflammatory changes are much less marked than after peripheral inoculation. This is due to a different type of pathologic process. Following intracerebral inoculation there is primary destruction of neurons, involving especially the hippocampus and also large areas of the neocortex. This change, similar to ischemic necrosis, is regarded in part as a nonspecific reaction of especially vulnerable tissue.

**Recovery from Lobar Pneumonia in Pregnancy.**—Musser and Boggs report the case of a woman seven months pregnant who recovered from type VIII pneumonia after specific serum therapy was given on the second day of illness. The patient was tested for sensitivity by the conjunctival method and the reaction was negative. She was then given 10,000 units of type VIII antipneumococcus serum prepared from rabbits' serum, two hours later she was given 40,000 units intravenously,

four hours later 40,000 units, and this was repeated in another four hours. The day after the serum was administered the patient's temperature was normal, her extreme cyanosis and dyspnea, which required oxygen, had disappeared and five days later she was discharged from the hospital entirely well.

**Surgical Treatment of Epilepsy.**—Evans states that the first requirement of selecting cases of epilepsy for surgical intervention is that the epilepsy be due to focal lesions in the brain. It might then appear that any generalized seizure would be excluded from consideration at the outset. This, however, is not always so, for it is conceivable that a seizure firing, for example, from one of the frontal poles, might work up its abnormal cerebral rhythm in a silent area of the brain and that the seizure would then spread rapidly, firing off the entire body musculature at one time. It is the usual rule, however, that cases of generalized seizures less often prove susceptible to surgical intervention. It is essential to analyze carefully both the subjective and the objective course of events in the patient's seizure and thus sort out by detailed analysis signs which indicate the initial area of abnormal discharge. Another criterion for the selection of cases suitable for surgical intervention is the pneumo-encephalographic evidence of focal damage. A third criterion is the finding at the site of suspected pathologic change variations of electrical potential characteristic of epileptic discharge. Use of this method depends on further elaboration of the methods of electro-encephalography. However, before radical excision of the suspected area is undertaken, a fourth criterion should be met—the production of a characteristic seizure by carefully controlled electrical stimulation of the exposed cortex. Finally, any patient should have, before operation is seriously considered, a thorough trial of phenobarbital or other sedative therapy, partly to avoid unnecessary operation, partly to prove that any postoperative sedation employed is not the cause of postoperative improvement rather than the operation itself. The aim of operative intervention is to excise the damaged area of the brain, leaving a lesser degree of damage than was caused by the original injury. This involves an understanding of the anatomic arrangement of the blood vessels and of the physiology of collateral circulation. The author concludes that the results of radical excision of cerebral cicatrix are, in his opinion, such as to justify further intelligent and critical pursuit of the problem.

**Preoperative Vitamin B<sub>1</sub> and Thyroidectomy.**—The evidence that a vitamin B complex or B<sub>1</sub> deficiency may play a part in the production of certain of the gastrointestinal disturbances, especially the anorexia often exhibited by the hyper-

thyroid patient, is discussed by Frazier and Ravdin. Several years ago they began the use of a vitamin B complex extract in patients suffering from hyperthyroidism. The patients were given large amounts of the extract with no other therapy during the period of observation. Although the basal metabolic rate was not reduced any more than in a control group, the general condition of the patients given the vitamin was better than the control group. The beneficial effects of the vitamin were compared with that of twenty-eight patients similarly treated in every respect except that no vitamin B was administered. The routine preoperative treatment was complete bed rest except for two hours daily, high caloric, high carbohydrate diet consisting of from 3,000 to 4,000 calories daily, from 5 to 10 minims (0.3 to 0.6 cc.) of saturated solution of potassium iodide three times a day, 0.65 Gm. of sodium bromide three times a day and 1½ grains (0.1 Gm.) of phenobarbital nightly. The fifty vitamin treated patients received in addition to the foregoing regimen 10 mg. of crystalline vitamin B<sub>1</sub> hypodermically every other day and 10 Gm. of brewers' yeast daily by mouth. Improvement in the vitamin treated patients, over the control group, occurred to the degree that the pulse rate was reduced during the period of preparation, patients gained weight and their appetite was increased and the length of time required for adequate preoperative preparation was shortened. These results are in agreement with the known effect of vitamin B<sub>1</sub> on the cardiovascular and gastrointestinal systems, if some degree of vitamin B deficiency exists. The two series of patients showed no significant differences in the lowering of the basal metabolic rate before operation or in the severity of the postoperative reaction. When improvement was noted in the vitamin treated series it was most marked in the more toxic group.

**Air-Borne Bacteria.**—Nisbet and Brooke found that the number of air-borne bacteria in the major surgery rooms of Multnomah County Hospital is roughly proportional to the number of persons present and to the activity on the floor proper of the surgery. The greatest proportionate rise in incidence is manifested by the streptococci and Staphylococcus albus. The organisms showing this rise are acknowledged to be common inhabitants of the nasopharynx. The estimated number of bacteria falling per hour on a sterile operating field compares unfavorably with similar figures obtained in other hospitals. The assumption that this increase is due in part to the agitation of air currents caused by the passage of the operating room assistants does not appear to be unwarranted. It is possible that some bacteria are carried into the surgery by the footwear.

### Tennessee State Medical Assn. Journal, Nashville 31: 381-424 (Oct.) 1938

**Sterilization of the Female.**—The Bowerses present a method for the sterilization of women for which hospitalization is not necessary. The procedure can be carried out in the office as it is only slightly more disturbing than cervical cauterization. After determining the necessity for sterilization, the patient is requested to be at the office a week or ten days after her regular menstrual period. She is instructed to take a copious douche of warm soda water an hour before her appointment. Following pelvic palpation she is left in the lithotomy position and a Sims speculum is introduced. The vagina and vaginal wall are thoroughly swabbed with a suitable antiseptic. The plug of mucus occluding the os is removed and the cervical canal is cleaned. A lip of the cervix is grasped with a tenaculum, and a catheter to which is attached a syringe with 10 cc. of radiopaque oil is inserted until its tip passes the internal os and the rubber olive fits snugly into the canal. The oil is injected slowly. The injection is discontinued, but the catheter is retained in position to prevent outflow of oil. A roentgenogram is taken and immediately developed, outlining the cavity of the tubes and uterus. The electrode employed is about 9 inches long and one-fifth inch in diameter; the distal end is semiflexible and is tipped with a small conical coil of platinum wire. Proxi-

mally there are two leads for electrical connections. The cauterizing coil at the tip is of platinum wire. To bring the cautery to a "cherry red" in air it was found that  $8 \pm 0.1$  amperes was required, corresponding to a consumption of 0.96 watt. The cautery electrode is then introduced, following the route previously outlined by the sound. Its active tip is snugly fitted into the uterine horn and by touch on its shank it is determined to be in contact with the mucosa on all sides. The current is then turned on for about forty-five seconds; meanwhile the active tip is given a slow rotary motion of a single revolution. This movement of the cautery tip prevents too deep a burn in one spot in the cornu and it causes the cauterization to be distributed about the entire funnel surface of the cornu, causing destruction of all the mucosa in this area and giving assurance against fistulous formation. It is important that the zone of coagulation extend into the muscular wall of the uterus, as it is here that the contracture is produced. The opposite side is similarly cauterized and a gauze sponge is left in the vagina to absorb the oily and sanguineous exudate, which the patient is instructed to remove when she returns home. Within a few days following the treatment there will be a serosanguineous discharge for a week or so which may necessitate a daily cleansing douche. Six weeks after the cauterization the patency of the tubes is checked either by air insufflation or roentgenologically. If the tube is closed, the cornu will be seen to be dome shaped and no oil will enter the tube. Contraindications for carrying out the procedure include any active infection of the genito-urinary system or any chronic infection of the tubes or uterus. Patients with malignant growths, fibroids, polyps and endometritis should not be treated with the cautery electrode. Of a series of twelve patients, six were cauterized once, five were cauterized twice and one was cauterized three times before closure was complete.

**Toxemia of Pregnancy Treated with Progesterone.**—McMann used a preparation of corpus luteum hormone in the treatment of eleven cases of toxemia of pregnancy. No other treatment was given. Labor was induced when the prognosis seemed precarious. The final results were disappointing. There were three absolute failures, two were questionable and six patients seemed to respond to treatment. The response, however, was greater than when the dehydration principles of Arnold and Fay, coupled with rest and strict attention to diet, are used.

**Endothelioma of Pleura.**—There is no general agreement that endothelioma of the pleura exists as a pathologic or a clinical entity. Barrett and Elkington do not enter into this controversy but rather point out and explain some physical signs which they found in two cases of diffuse new growth of the pleura. In both cases a careful postmortem examination was made. In neither was a primary tumor demonstrable in the bronchial tree nor was there any evidence of lymphatic invasion in spite of the fact that the growths were extensive. In the second case malignant cells were found in the sputum before death, and these were diagnosed as from an endothelioma. At the postmortem examination of this case it was obvious that the malignant tissue was invading the bronchi from without, and paraffin sections showed the mucosa intact in places in which collections of malignant cells had penetrated between the cartilaginous rings and extended along the submucosa. The fact that malignant cells were ultimately demonstrable in the sputum is not necessarily an argument in favor of the suggestion that this was a primary bronchial growth. From the clinical point of view, both these tumors gave physical signs which were difficult to interpret in the early stages. In each case the respiratory signs pointed to a marked, progressive and diffuse thickening of the pleura, with little evidence of involvement of the lung itself. The nervous signs were strikingly similar. They consisted of wasting and complete paralysis of certain of the intercostal muscles on one side and also of the upper segment of the abdominal recti and oblique muscles. In each case the diaphragm on that side was immobile.

**Granulomatous and Tuberculous Gastric Ulcers.**—Kini and Narasimha Rao state that when extensive shallow ulcers with undermined edges occur in the pyloric region it becomes difficult to differentiate them from malignant disease of the pyloric antrum. After gastrectomy one of the three ulcers in their series, which appeared to the naked eye to be typically tuberculous, failed to show on microscopic examination any evidence of tuberculosis (case 3). Case 1 was diagnosed as a case of malignant disease and a gastrectomy was performed. It was only after gastrectomy that the ulcer was found to be granuloma-

tous, resembling a tuberculous ulcer, which on microscopic examination it was suspected to be. In case 2 no gastrectomy could be performed, as the general condition of the patient was poor. While gastro-enterostomy was being performed, a good view of the ulcer could be obtained through the stoma. It resembled the ulcer in case 1. The gland removed for biopsy was suspected to be tuberculous on microscopic examination. Case 3 resembled the first in all its aspects, but on histologic examination there was no evidence of tuberculosis in the sections examined. A gastrectomy was performed.

**Pathology of Ménière's Syndrome.**—Hallpike and Cairns describe the microscopic changes in the temporal bones of two patients with Ménière's syndrome. In each of these the affected temporal bone showed a gross distention of the endolymphatic system together with degenerative changes in the sensory elements. A possible explanation of this distention is suggested by the absence in both patients of the normal area of perisaccular connective tissue around the saccus endolymphaticus. A possible mechanism is further suggested whereby the microscopic changes may be correlated with the clinical features of the disease.

**Chloride Content of Blood Serum and Aqueous Humor.**—Hodgson determined the chloride content of the aqueous humor and blood serum of man and dogs by the ultramicro silver iodate method. The values for a group of nonglaucomatous human beings averaged, in millimols per liter, aqueous 124.3, serum 105.1. There was no significant difference in the values obtained in cases of primary chronic glaucoma with high intra-ocular tension in which the average values were 126.3 for aqueous and 106.5 for serum. Normal unanesthetized dogs gave average values of 127.6 and 109.1, respectively. The high values

obtained for aqueous chloride show that there is no Donnan equilibrium for this ion between the blood and the aqueous humor, so that the latter cannot be regarded as a dialysate.

**Intestinal Absorption and Excretion of Iron.**—McCance and Widdowson discuss experiments planned to determine whether or not the intestine of a normal human being can excrete iron and by so doing regulate the amount of iron in the body. The investigation consisted of three stages: diets containing daily from 5.9 to 8.6 mg. of iron, from 12 to 16 mg. of iron and from 7.6 to 11.7 mg. in addition to 7 mg. of iron intravenously. Within the limits of experimental error none of the injected iron was excreted into the gastrointestinal tract. About 1.4 per cent of it was excreted in the urine, but it is believed that this is of no practical significance in iron metabolism. The results are considered to confirm the theory that the intestine has no power of regulating by excretion the amount of iron in the body. The three normal women were not in positive iron balance in their intermenstrual periods. It would be interesting to know at what time during the menstrual cycle these women absorbed the iron necessary to make good their loss.

**Health of Women.**—Bourne states that a great volume of the minor but chronic ill health of women is due not so much to the major difficulties or injuries of reproduction or even to the peculiar susceptibility of the pelvic organs to disease but to the wearing influence of a mass of minor worries incidental to their domestic and family life. Two main influences may affect the spinster's health. The first, a deep disappointment of the maternal instinct coupled with an underlying fear of economic insecurity, is liable to express itself physically in neurosis. The author believes that the majority of women who have not found a mate, and who have no absorbing work or object on which to exert their desire for service, do suffer in a way that will ultimately express itself physically. In the second influence it is probable that the exclusion from activity of the large element of a woman's physiologic function, as represented by her sexual organs, reacts on those organs and also on the rest of her body. It is difficult to believe that the endocrine system, so important a part of a woman's economy, can fail to suffer some impairment if the major portion of its function has never been used.

**Atropine Paralysis During Examination of Digestive Tract.**—Bernard and Monnier employed duodenal dilation by injection of atropine in all roentgenologic examinations of the digestive tract. The technic is as follows: At first the roentgenologic examination of the stomach is made according to the customary method; that is, a series of roentgenograms is made while the patient is standing and reclining. This procedure is followed by the subcutaneous injection of 1.5 mg. of neutral atropine sulfate, and from ten to twenty minutes later a new series of roentgenograms is made while the patient is in the erect and then in the reclining posture. Apart from a certain dryness of the oral mucosa in some instances the authors did not observe any inconvenience from this method. They employed it in seventy-six cases. Summarizing their observations, they state that the injection of atropine in the course of the roentgenologic examination of the digestive tube paralyzes and dilates the stomach, the pylorus, the duodenum, the jejunum and the colon. The transit of barium is retarded and the different organs are well filled and are in an optimal condition of stability for the x-ray film to record their pathologic deformities. Every parietal lesion, neoplasm, ulcer or condition of perigastritis remains uninfluenced by atropine. Consequently the absence of atropine paralysis of a segment of the digestive tube is an indication of an organic lesion. On the other hand, the deformities which disappear under the action of atropine can be considered as of a spasmodic nature. Thus the method permits a definite differentiation between functional and organic disorders. The atropine method brings into evidence more clearly neoplastic lacunas, gastroduodenal ulcers, diverticula and duodenal malformations. Moreover, it involves no danger and merits to be introduced into routine roentgenologic practice.

### Journal de Médecine de Lyon

19: 591-622 (Oct. 20) 1938

- \*Curves of Sedimentation and of Serologic Reactions in Pulmonary Tuberculosis Treated by Pneumothorax: Prognostic Significance. P. Courmont and J. Moulinier.—p. 591.  
Ascorbic Acid (Vitamin C) and Tuberculosis. A.-A. Policard.—p. 611.

**Sedimentation and Serologic Reactions in Pulmonary Tuberculosis.**—Courmont and Moulinier point out that the prognosis of pulmonary tuberculosis must be based on the serologic reactions, especially on the agglutinating power, the deviation of the complement and the bactericidal power in comparison with the clinical factors and with other reactions such as Vernes' resorcinol flocculation and the sedimentation speed. The demonstration of the value of these tests and especially their curve throughout the course of disease is simple in the acute, localized forms which are rapidly cured by pneumothorax treatment; conversely the prognosis is facilitated by these serologic curves. The authors cite the serologic curves of twenty-seven patients who were treated with pneumothorax. In fifteen only the curve of the sedimentation speed was investigated, but in the other twelve all five reactions were studied and especial attention was given to the comparison of the sedimentation speed and the agglutinating power. Some cases were observed for several years, the tests being made frequently, in many instances at monthly intervals, because the prognosis of tuberculosis is estimated in years. Isolated figures of the reactions have less value than the curves, yet an increase in the sedimentation speed and in Vernes' resorcinol reaction has an unfavorable significance at the time they are observed, whereas an

increase of the agglutinating power and of the bactericidal power is a favorable sign. The patients with pneumothorax who have a high agglutinating power are nearly always cured. The curves plotted on the basis of repeated tests and especially their comparison are of especial value. The curves of the sedimentation speed and of Vernes' resorcinol reaction have an analogous significance. They are elevated in the grave periods and at the time when complications develop; they decrease at the time of cure. Their prognostic significance is slight, because it is limited to the present time. The curves of the bactericidal power and especially of the agglutinating power are more important. Their progressive elevation signifies an excellent prognosis; on the other hand, if they are low, and especially if they decrease in the course of pulmonary tuberculosis and of pneumothorax therapy, the prognosis is unfavorable; that is, a fatal outcome may follow within several months. The serologic tests must be evaluated in connection with the clinical, roentgenologic and bacteriologic factors; they are not only helpful in fixing the prognosis but are also valuable in making decisions regarding the conduct and cessation of pneumothorax therapy and in deciding certain surgical interventions (section of adhesions, thoracotomy and so on). The easiest and most demonstrative of the serologic tests for the practice are the sedimentation speed and the agglutinating power, the latter being the most valuable. The comparison of their curves gives the best results, the sedimentation speed indicating the severity of the infection and the agglutinating power the defense of the organism.

Esophageal Diverticulum: Case. Estève.—p. 505.

**Anomalies of Vertebral Articular Processes.**—Willemin and Cantagrill call attention to the difficulties that are encountered by the roentgenologist in the interpretation of spinal roentgenograms. They cite a case in which an anomaly of vertebral articular processes existed which, although rare, may be of great medicolegal significance. The anomaly consists in accessory articular processes on the vertebrae, and the division in the continuity at the level of the vertebral articular processes may lead to confusion with fractures of the articular processes. The patient whose history is reported had accessory articular processes on the second and third lumbar and on the first sacral vertebrae. Following a detailed description of the roentgenologic aspects, the authors review the recent literature on these vertebral anomalies, giving special attention to Wilbur Bailey's report (*THE JOURNAL*, Jan. 23, 1937, p. 266). Bailey found nineteen cases of this anomaly in the literature, six of which presented bilateral lesions. The authors, in addition to the case which they describe and in which the anomaly was detected on three vertebrae, observed another case with an isolated accessory articular process. After citing other opinions on the incidence of the accessory vertebral articular processes, they point out that these abnormal centers of ossification are usually found on the inferior articular processes and that they are exceptionally rare on the superior articular processes.

Pancreas of Tuberculous Patients. M. Loeper and R. Lesobre.—p. 1569.

\*Treatment of Male Gonorrheal Urethritis. P. Durel.—p. 1571.

**Treatment of Gonorrheal Urethritis.**—Durel discusses the use of various sulfanilamide preparations in the treatment of gonorrheal urethritis. For the treatment of subjects who are not benefited by the local treatment of gonorrheal urethritis he suggests three different possibilities. First he mentions the administration of large doses of 1162 F (*p*-aminophenylsulfanilamide), saying that he has given 4 Gm. a day for five days,

3 Gm. a day for five days and 2 Gm. a day for five days. He emphasizes that this posology requires careful supervision and he does not advise it for routine use. A second possible treatment is the combination of 1162 F in weak doses and 40 R. P. (soluseptazine, that is, disodium-*p*-(gamma-phenylpropylamino) benzenesulfonamide-alpha-gamma disulfonate. The 1162 F is given for seven days in daily doses of 2 Gm., and 20 cc. of soluseptazine is given daily by intramuscular injection. This treatment may cause slight complications and the author does not consider it of great practical interest. The third method suggested is the use of sulfanilamide-pyridine. Following a description of its formula and its behavior in animals, the author describes the clinical results obtained with it. By one method the patient is given 13 Gm. of the medicament in the form of tablets over a period of eight days (two days 3 Gm. each, two days 2 Gm. each, two days 1 Gm. each and two days 0.5 Gm. each). The second method provides 18 Gm. in nine days (3 Gm. for three days, 2 Gm. for three days and 1 Gm. for three days). The third method provides 20 Gm. in eight days (4, 3, 2, and 1 Gm. for two days each). The second type of dosage seems to be suitable in the majority of cases but the author thinks that the future will doubtless modify these methods. Discussing the results obtained with sulfanilamide-pyridine he states that in acute gonorrheal urethritis in males more than 80 per cent of cures were obtained. Of the prolonged cases of urethritis about 70 per cent were cured. In women with metritis of the cervix the results have not been established as yet, but they seem superior to those obtained with other sulfanilamide preparations.

Appearance of Schizophrenic Exacerbation After Psychic Trauma. R. Mayer.—p. 88.

**Little's Disease and Epilepsy.**—Biro directs attention to the fact that epileptic attacks develop as accompanying symptoms of various disorders. He investigated the epileptic attacks that occur in patients with Little's disease. He says that not all convulsive attacks that occur during Little's disease can be regarded as epileptic but that attacks of an epileptic character do occur in this disease. He observed them in ten of thirty-five patients with Little's disease. The attacks usually developed during the early part of the disease. In some of the cases they preceded the other symptoms by from 3.6 to ten months, in others by only one or two days and in still others they appeared simultaneously with the symptoms of the disease. Irrespective of their time of appearance, they ceased in some of the patients during the further development of the disorder; in others they continued, with intervals, for weeks, months or years. The fact that epilepsy appears in the form of attacks proves that physiologic secondary effects are involved. Endocrine disturbances in women, in whom the attacks recur monthly, and disturbances in the intracranial pressure occasionally make it possible to detect a parallelism between those disturbances and the epileptic attacks. The frequent occurrence of the attacks during sleep, that is, during a periodic process, as well as the intermittent character of the epilepsy may be connected with the sympathetic centers in the diencephalon. In the cases reported by the author, the epileptic attacks occurred during the hemiplegic as well as during the diplegic syndrome, in which pyramidal, extrapyramidal and mixed disturbances predominated. Among the patients with Little's disease who had epileptic attacks there were many who also had psychic disturbances. However, the incidence of the psychic disturbances was not higher than in other patients with Little's disease. In many of the cases of Little's disease with epileptic attacks, no anatomic basis could be found for the attacks. It is difficult

to make a definite prognosis regarding the reappearance of the attacks, even after prolonged observation. The treatment of the epileptic attacks in Little's disease should be like that of cryptogenic or of jacksonian epilepsy.

\*Influence of Lecithin and Lutein on Hypoglycemic Action of Insulin in Diabetes Mellitus. G. Pavan and C. Moro.—p. 994.

**Lecithin and Lutein in Diabetes.**—Pavan and Moro studied the influence of lecithin and lutein on the hypoglycemic action of insulin. In sixteen normal children and six normal rabbits the authors induced hyperglycemia by means of the administration of sugar and followed the behavior of hyperglycemia in the course of a test which consisted in the administration of an intramuscular injection of insulin alone, a lecithin and lutein preparation alone, lutein alone or insulin in association with any of the substances mentioned. In four children who were suffering from diabetes (mellitus or renal) the behavior of glycemia was followed after administration of either insulin alone, the lecithin and lutein preparation alone or insulin in association with this preparation. The authors found that the lecithin lutein preparation has a hypoglycemic action in normal children and in normal rabbits. Lutein has a slight hyperglycemic action, which is due to the fact that the substance on the market contains cholesterol. The lecithin lutein preparation when it is administered to children who are suffering from diabetes either after insulin or in association with it increases the therapeutic action of insulin, makes easy, slow and continuous assimilation of the drug by the patients, acts on the glycemia for several hours and thus prevents hypoglycemia. When insulin in association with the lecithin and lutein preparation is administered for about a month to patients suffering from diabetes, the figures of glycemia during fasting diminish. The dose of insulin can be reduced by this time. According to the authors, lecithin and lutein in diabetic patients stimulate transformation of dextrose into glycogen and also the capacity of the liver and muscles for storing glycogen.

\*Estrogenic Substance in Treatment of Vulvovaginitis in Little Girls. L. Hoeppner Dutra.—p. 326.

**Vulvovaginitis in Little Girls.**—Hoeppner Dutra reports satisfactory results from the administration of estrogenic substance (progynon B) in the treatment of vulvovaginitis in twelve girls ranging in age from 2 to 10 years. The condition was gonorrheal in ten cases. The substance is given in intramuscular injections, once a week, at a dose of 10,000 international B units (U. B. I.) up to a total number which varies from one to three (and in rare cases four) injections. A vaginal lavage of a 1 per thousand protein silver solution is administered with a short fine sound every other day during the treatment. The mothers of the patients are instructed to put the patients in a sitz bath of tepid water for a few minutes every night. Generally the discharge stops and the gonococcus disappears from the secretion after the third injection. The evolution of the condition is controlled by making weekly examinations of smears prepared from the vaginal discharge. As the treatment advances the number of leukocytes and pus cells diminish in the secretion, the cells of the vaginal epithelium become vacuolar and cornified and the flora of the secretion becomes normal. In two of the cases seen by the author there was a complication of gonorrheal conjunctivitis which was rapidly controlled by the proper local treatment under the influence of the estrogenic treatment. The latter has an average duration of three or four weeks. It is not followed by complications. Recovery of the patients is permanent. According to the author the estrogenic treatment has a biologic action by which a cellular proliferation of the vaginal epithelium is stimulated, the reaction of the vaginal discharge is favorably modified (acidity) and the vaginal mucosa is regenerated.

**Respiration and Blood Oxygen During Pregnancy.**—During pregnancy, according to Borgard and Effkemann, respiration is altered in two respects: 1. As a result of the elevation of the diaphragm, the deep inspiration is mechanically impaired, the volume of the individual respiration is reduced and as a compensation the respiratory frequency is increased. 2. The total extent of the ventilation, the respiratory minute volume is greater than corresponds to the increased oxygen requirements of pregnancy (increase of basal metabolism during pregnancy). It has been pointed out repeatedly that the respiratory minute volume is increased by from 10 to 20 per cent during pregnancy. The authors subjected pregnant women to work tests in order to determine whether work requires a percental increase in the respiration compared to normal conditions and to what extent a changed oxygen combining power of the blood influences the respiratory minute volume. In a table the authors show the results which they obtained in twenty-seven tests. A comparison with the normal values of nonpregnant healthy women revealed that, with the same exertion, the respiration of pregnant women is considerably greater, although the absorption of oxygen per time unit is reduced as a sign of the decreased circulatory capacity during pregnancy. These quantitative determinations seemed necessary as a foundation for the investigation as to why the ventilation is increased during pregnancy. It was found that the increase in ventilation is due to an impairment of the conditions of arterialization in the blood. The curve recording the oxygen combining power of the blood of pregnant women is displaced toward the right even during rest; that is, a higher oxygen tension in the alveolar space is required than is the case in the absence of pregnancy. During exertion, the curve of the oxygen binding power of pregnant blood is essentially more toward the right than that of nonpregnant women.

**Latent Period of Incipient Cervical Carcinoma.**—In this extensive report, Scipades and Stevenson review the literature on the problem of the beginning cervical carcinoma and report their own extensive studies. Summarizing their observations, they say that on the basis of cases that were selected from a clinical material over a period of twenty years it can be stated that the incipient cancer passes through a period in which there are no symptoms and the growth is not progressive. This latent period lasts at least six months and it may last six or even eight years, the average being about 3.9 years. The authors observed further that the carcinomas, which were detected early by means of exploratory excisions and which were treated by extirpation of the cervix, by radium irradiation or a combination of the two methods were always cured. Finally the authors demonstrated that the hyperactive epithelial changes can be regarded neither as precancerous conditions nor as incipient cancers, because they never developed into cancers. They gained the impression that these epithelial changes, just like the leukoplakias of the cervix, are fluctuating manifestations which, under the influence of different factors, may develop and disappear again. They say that it has been asserted that the surgical as well as the radiation therapy of the completely developed carcinoma has reached the limits of its possibility. They show that, if this is so, the only hope for further improvement is the earlier recognition of the carcinoma and they believe that the test developed by Schiller (staining with compound solution of iodine) and the colposcope devised by Hinselmann are valuable aids in facilitating an early diagnosis.

- Differentiation of Whooping Cough Bacilli and Influenza Bacilli. A. Steigler.—p. 1480.

**Triboulet's Reaction.**—Wiesbrock points out that Triboulet's reaction is used chiefly for the diagnosis of intestinal tuberculosis but that, although it produces positive reactions in all cases of intestinal tuberculosis, it results in such reactions also in a large number of disorders and therefore cannot be regarded as specific for intestinal tuberculosis. In studies on seventy-four patients in whom intestinal tuberculosis was suspected, the author gained the impression that the protein bodies are demonstrable in the intestine in especially severe infections and intoxications. In order to throw more light on this problem, he made Triboulet's test on all specimens of feces, 550 in all, which were submitted to him for bacteriologic examination in order to detect typhoid, paratyphoid or dysentery. In this material seventeen cases of typhoid were detected and the positive bacteriologic test was accompanied by a positive Triboulet reaction. In thirty-five cases of paratyphoid, in ten cases in which bacilli of the Breslau type were found, in sixteen of dysentery, in fourteen bacillus carriers and in a number of cases negative to bacteriologic examination Triboulet's reaction was found to be positive. It was also noted (although not always) that Triboulet's reaction produced a somewhat different type of precipitation in dysentery than it did in paratyphoid. Whereas the latter usually yielded a coarse precipitate and a clear supernatant fluid, the precipitate of dysentery often showed a fine granulation and a more or less clear supernatant fluid. Thus it was frequently possible to foretell the outcome of the bacteriologic test from the results of Triboulet's reaction. The author thinks that, if his observations should be corroborated by others, Triboulet's reaction could be employed as a diagnostic aid in infectious diseases of the intestine. The bacteriologic examination is often difficult, because bacilli are not always excreted with every stool. The author thinks that in large material it might perhaps be advisable first to subject the stools to Triboulet's test and then to make bacteriologic tests only on specimens in which Triboulet's reaction proves positive.

**Pregnancy Polyneuritis and Vitamin B<sub>1</sub>.**—Hildebrandt and Otto direct attention to the fact that treatment with vitamin B<sub>1</sub> is of great value in the polyneuritis of pregnancy. They report the clinical history of a woman who developed a severe polyneuritis during pregnancy. They instituted treatment with vitamin B<sub>1</sub> and vitamin C. The woman received during her pregnancy a total of 1,782 mg. of vitamin B<sub>1</sub> and there were no disturbing secondary effects such as premature elicitation of labor pains or symptoms of excessive dosage. The pregnancy terminated in the birth of a healthy child. Tests on the urine of the woman disclosed that up to the delivery no vitamin B<sub>1</sub> was eliminated in the urine and vitamin C was excreted in small quantities. Later, however, nor-

mal secretion was observed and vitamin B<sub>1</sub> could be detected in the serum. Not only did the administration of vitamin B<sub>1</sub> improve the pregnancy polyneuritis but the subacidity of the gastric juice and the hypochromic anemia were counteracted; the fasting blood sugar was slightly influenced (temporary slight decrease) and a hepatic disturbance was compensated. The authors conclude that, in the presence of severe paralytic symptoms during pregnancy, treatment with vitamin B<sub>1</sub> should always be tried before an interruption of the pregnancy is decided on.

**Phosphate Concrements of Urinary Tract.**—Jensen and Thygesen discuss recent developments in the chemistry of calcium phosphates and describe their studies on thirty-five phosphate calculi that had been obtained in renal and vesical operations and in the course of necropsies. In the qualitative analysis, sections of the calculi were pulverized and 0.25 Gm. of this powder was examined for carbonate, ammonia, phosphate, oxalate calcium and magnesium and in some cases also for uric acid and albumin. The analyses were always made in the same manner and the reactions were compared among one another and with the reactions of known quantities of pure substances. This method permits a rough estimate of how much of the various substances is contained in the calculi. The authors give an example of such an analysis. Further, roentgenologic diagrams were made of the pulverized calculi. These diagrams were then compared with the results of the analyses. In a few instances, diagrams were made also of the residue on ignition. The authors detected the following substances in the calculi: (1) magnesium ammonium phosphate, (2) a colloid-like calcium phosphate with incomplete apatite structure, which contains between three and three and one-half equivalents of calcium per mol of phosphoric acid and some closely bound water, and (3) beta-tricalcium phosphate. Those mentioned under points 1 and 2 are the usual constituents of phosphate calculi and they are found more frequently mixed than pure. Two calculi consisted of beta-tricalcium phosphate. So far it has not been possible to extract beta-tricalcium phosphate from aqueous solution but only by direct reaction between calcium oxide (CaO) and phosphorus pentoxide (P<sub>2</sub>O<sub>5</sub>) under high temperature. Calcium carbonate, normal magnesium phosphate and the secondary calcium phosphates, which are often designated as the usual constituents of phosphate calculi, were not detected.

- Mucineal Manifestations in Presence of Ascarides. C. J. Wijckerheld Bisdorf.—p. 490.

**Bacillary Dysentery in Young Nurslings.**—Lammerts van Bueren and de Haas report that among 400 children with bacillary dysentery observed at the children's clinic in Batavia there were 160 nurslings and eleven of these were less than 3 months old. On the basis of the clinical observations on these eleven young nurslings and of the bacteriologic examination of their feces, the authors conclude that bacillary dysentery may attack nurslings during the first three months of life, irrespective of whether they are bottle fed or breast fed. The course of the bacillary dysentery in these young nurslings is changeable and may even be fatal, just as in older children. Regarding

the etiology, the authors say that in the nurslings of the first quarter of life the same bacilli, the so-called pseudodysenteric bacilli, are encountered that are found also in the older children with bacillary dysentery. The dysenteric character of the feces is usually less pronounced in the young nursling than in older children. The diagnosis of bacillary dysentery requires the microscopic examination of the feces in the young nurslings as in the older children. It reveals a greater or lesser number of leukocytes and a few or no erythrocytes. The treatment of bacillary dysentery should be dietetic even in the young nurslings. Little or no medicaments should be given.

**Investigations of Vitamin C.**—Herlitz used the modified Lund and Lieck method of determining the content of ascorbic acid in the blood serum in forty-four healthy children without gingivitis and fifty-seven children with severe gingivitis, between the ages of 3 and 16 years, after the oral administration of 10 mg. of ascorbic acid per kilogram of body weight. It was found that the ascorbic acid content of the serum increased in the same degree to which raw fruit was added to the diet. This signifies an indirect control of the reliability of the food anamneses. The average fasting value for children who were given a moderate supply each day of raw fruit (approximately one orange or apple) in addition to an otherwise normal diet was  $0.71 \pm 0.073$  and the two hour value, after loading, was  $1.87 \pm 0.111$  mg. per hundred cubic centimeters of serum. The corresponding figures for children who, under otherwise similar conditions, seldom or at most received raw fruit only once a week were  $0.24 \pm 0.025$  and  $0.69 \pm 0.05$  mg. respectively. When the fasting values lie below 0.4 and, simultaneously, the two hour value is below 1 mg. the child has probably been receiving food poor in vitamin C content or a subnormal vitamin C standard is present. The existence of this combination of values does not in itself permit the diagnosis of scurvy. The probability that gingivitis has any connection with subnormal ascorbic acid was not elicited but that this condition must be referred to some other etiologic factors is suggested. Extremely low serum-ascorbic acid values may be made to rise to a normal level in three weeks by adding fruit to the diet in moderate amounts.

### Ugeskrift for Læger, Copenhagen

- \*Simple Urethritis or "Catarrh of Urethra": Comparative Experiences and Considerations on This Disease and Gonorrheal Urethritis. V. Genner.—p. 1069.  
\*Treatment of Infections of Urinary Tract with Calcium Mandelate: One Year's Experiences. E. Schnohr and C. Johansen.—p. 1074.  
Infections of Urinary Tract Treated with Granulate of Calcium Mandelate. K. Rasmussen.—p. 1082.

**Simple Urethritis and Gonorrheal Urethritis.**—Genner says that, while simple urethritis in women is hardly as rare as commonly thought, his comparative statistics on this disorder and gonorrheal urethritis in more than 100 cases in men show a frequency ratio of 1 to 2. He asserts that the form of simple urethritis designated as "postgonorrheal catarrh" now constitutes only a small percentage of the total number of cases; its probable greater frequency formerly is ascribed to the more irritative treatment of gonorrhea then used. In about one third of the cases of simple urethritis there was history of earlier gonorrhea, but as a rule far back and without direct connection with the simple urethritis. Sulfanilamide seems to him an important addition to treatment.

**Urinary Tract Infections Treated with Calcium Mandelate.**—Schnohr and Johansen used calcium mandelate in the treatment of sixty patients with infections of the urinary tract. The dose was 12 Gm. daily and the amount of fluid ingested

was limited to 1 liter daily. In thirty-nine cases the urine became sterile, in thirty-one after a week or less, in five after from nine to thirteen days, in three after twenty, twenty-five and sixty-five days respectively. In thirteen cases the subjective symptoms disappeared although the urine did not become sterile. The treatment was without effect in eight cases (six with complicating disorders, one with a history of ureterotomy, one in a pregnant woman given only two days' treatment). The urine became sterile in seven of twenty patients in whom the infection was a complication in a grave disorder of the urinary tract and in eight of thirteen cases with milder complications. The bacillary infection was eliminated in thirty-four of forty-seven cases with *B. coli* infection, in two of nine cases with *B. proteus* infection and in some cases with infection with staphylococci, gram-positive cocci and hemolytic streptococci. In most cases the  $pH$  in the urine was reduced to between 4.8 and 5.3. As a rule the urine did not become sterile until the  $pH$  was 5.3 or less, it was never sterile when the  $pH$  was over 5.5. In six cases in which the  $pH$  remained between 6 and 8 the addition of from 3 to 6 Gm. of ammonium chloride daily brought the  $pH$  to about 5 in four and the urine became sterile in two. Except for a transitory hematuria in one instance, treatment with calcium mandelate caused no injurious effect on the kidneys although the renal function was impaired in several cases. Only two patients were unable to take the granulate because of gastric symptoms. Occasionally nausea occurred after some days' treatment, and in two cases there was nausea during the first days.

Condition of Teeth at Bornholm. II. C. Olsen.—p. 1116.  
Contact Ulcer. G. Hagerup.—p. 1117.

**Osteomalacia of Spinal Column.**—Meulengracht reports eighteen cases of osteomalacia in which the changes were localized chiefly in the spinal column. The subjective symptoms were pain in the back and groins, occasionally in acute attacks (spontaneous fractures). External examination established a settling of the back sometimes with kyphosis or lordosis. Often there was considerable decrease in height. Roentgen examination showed calcium deficiency in the skeleton, most marked in the spinal column; the vertebrae were low, biconcave or more irregularly deformed. Sometimes there was also a roentgenologically demonstrable osteo-arthritis of the spinous process (Baastrup's disease) in the lumbar region, originated through the settling and shortening of the lumbar column. The changes are in some of the cases attributed to diet deficient in calcium and vitamin D; in the other cases gastric achylia or misuse of laxatives is believed through changed conditions of resorption to have been the contributing cause or the main cause for the development of the symptoms. Treatment with calcium salts and vitamin D proved effective.

- \*Effect of Dextrose on Tar Tumors in Mice. K. A. Vannfält.—p. 267.  
Roentgen Symptoms in Abdominal Injuries through Blunt Force. II. Laurell.—p. 413.

**Effect of Dextrose on Tar Tumors in Mice.**—Vannfält studied the effect of feeding 50 per cent dextrose solution on the growth and metastasis of tar tumors in mice and the length of life of the animals. In the females given dextrose there was a statistically established checking of metastases to the regional lymph nodes and to the lungs. In the mice with cancerous skin tumors the control group showed a statistically greater frequency of metastases (without regard to their localization) than the mice fed dextrose. The resistance of the animals with malignant tumors which expresses itself in greater length of life is considered a biologic indicator of the degree of malignancy. Since the animals given dextrose lived longer, the author thinks it probable that the tumors were less malignant than in the control group. Investigations on the effect of insulin on tar cancers in mice indicated that in the daily dose of 0.02 clinical unit it exerted no certain influence on the time of appearance of the tumor, its malignant degeneration or metastasis to the regional lymph nodes or internal organs but shortened the lifetime of the animals.

## ALLERGY IN CHILDHOOD

### III. ITS ONSET AND NATURAL PROGRESS

BRET RATNER, M.D.  
NEW YORK

Many factors that enter into the problem of the initiation of allergy have been considered in a previous paper of this series in which the various modes of acquisition were treated.<sup>1</sup> Here attention will be directed mainly to certain observations relative to the early beginnings and the natural course that allergy follows with increasing age. I have limited my observations to the four major syndromes eczema, asthma, hay fever and urticaria. A correlation of such observations, I believe, will help in the early diagnosis of these conditions and, if properly treated, should tend to abort further progress of the allergic syndromes.

#### THE ONSET

Practically all students concerned with allergy in adults find that from 50 to 60 per cent of their patients give a history of onset in childhood. The early careful observations of the beginnings of allergy, however, were first made by pediatricians, among whom should be mentioned Schloss,<sup>2</sup> Talbot<sup>3</sup> and Blackfan.<sup>4</sup>

In a series of 250 allergic children, my associates and I found that 50 per cent had symptoms in the first year; by the fifth year 80 per cent manifested syndromes, and between the eighth and tenth years allergy was already established in practically all our patients.

A direct approach to the study of the onset of allergy can best be served by an analysis of the group of allergic infants who were under 1 year of age. The family history was positive in only 52 per cent of the cases, indicating that there are just as many infants without an allergic family history who have an early onset of allergy as those with a positive history.

Cooke and his co-workers<sup>5</sup> adduced from their studies that the greater the degree of inheritance, the earlier will be the onset of allergic phenomena. The studies of Cooke, however, were largely concerned with

adults, the majority of whom suffered from hay fever. Studies on asthma by Bray,<sup>6</sup> Peshkin<sup>7</sup> and O'Keefe<sup>8</sup> dealing exclusively with children and our own observations on general allergy in childhood lead us to conclude that the age of onset is not as strongly influenced by heredity as is generally believed. It cannot be denied that there are more affected children in a small percentage of families (in our series in about 12 per cent) with a strong familial allergic tendency than in those in which this tendency is absent. While one may have to admit that a greater susceptibility for allergy does exist in certain children, it does not appear that the actual age of onset is influenced solely by genetic factors.

In the infants under 1 year of age, eczema was the presenting syndrome in 90 per cent. The remaining 10 per cent suffered from asthma. Though of the cases recorded the youngest patients with asthma were respectively 14 and 28 days old,<sup>9</sup> this early onset apparently is not the rule. Of our patients with asthma under 1 year of age, the average age at onset was 7.3 months. As I shall show presently, however, the overwhelming majority of cases start after the first year. As compared with asthma, there is a striking difference in the age at onset of eczema in infants under 1 year, which was 1.9 months. It is also interesting to note that the average age at the time of observation was 6.5 months for the patients with eczema and 9.6 months for patients with asthma under 1 year. It is apparent from these figures that eczema is the prevailing allergic condition in infancy and that it starts considerably earlier than any other syndrome. This is not a signally new observation; as a matter of fact, it is generally accepted as being axiomatic.

We found a surprisingly high degree of cutaneous reactivity among our patients under 1 year.

Some of the youngest patients for whom positive cutaneous reactions were reported were those of Balyeat,<sup>10</sup> who tested 119 normal newborns with egg, milk and wheat at 3 days of age. For one infant he obtained a four plus reaction to wheat which lasted one hour and ten minutes. Another gave an unquestionable three plus reaction to egg which persisted for fifty minutes. Smyth and Bain<sup>11</sup> found no positive reactions among 125 normal newborns. This is not surprising, for Peshkin and Rost<sup>12</sup> found only 10 per cent doubtful

or positive reactions in a large group of normal children, the youngest group being between 2 and 5 years of age. Blackfan<sup>13</sup> found only one positive cutaneous reaction among forty-three normal individuals, that one instance occurring in an infant 9 weeks of age.

Balyeat's finding, which must be regarded as extremely fortuitous, however, is of importance, for it indicates that a positive reaction can be obtained in a newborn infant, and it must be presumed, as Balyeat himself suggests, that sensitization must have occurred in utero.

Blackfan reports a positive reaction in an allergic child at 5 weeks, Lyon<sup>14</sup> at 6 weeks, Shannon<sup>15</sup> at 8 weeks and Smyth<sup>11</sup> at 11 weeks. In our own series, we had three eczematous infants, one as young as 9 weeks and two who were 12 weeks old, who showed cutaneous sensitivity. Stuart and Farnham<sup>16</sup> infer that hypersensitivity to food proteins tends to be present at birth.

Positive reactions were obtained in 85 per cent of the patients under 1 year of age. While 100 per cent reacted to foods, only 41 per cent reacted to foods alone, whereas 53 per cent reacted to foods, inhalants and contactants and 6 per cent reacted to these and pollens in addition.

Sensitivity to foods is a common observation of those working with infants. In fact, the preponderance of positive reactions to food tests in the first year has led certain investigators to suggest that the infants become sensitive when these foods are eaten. Smyth<sup>17</sup> aptly takes objection to this point of view. Egg white, which stands first in order of frequency in positive reactions, is not introduced into the diet as early, nor in the same quantity, as is cow's milk, to which many fewer infants react.

Our concept of active intra-uterine sensitization—owing to the passage of undigested food protein from the maternal blood stream to the fetal circulation by way of the placenta—offers a plausible explanation for those cases of food reactors who have never eaten the food prior to being tested, or for those who manifest allergic reactions the first time the food is consumed. This concept, which I<sup>18</sup> voiced in 1928, has corroboration in the earlier observations of Schloss and Worthen,<sup>19</sup> Blackfan<sup>4</sup> and many others, who report cases in which positive reactions to egg white were obtained in infants who had never eaten eggs. Schloss<sup>20</sup> observed that in sixteen cases out of thirty-three symptoms developed the first time some food was eaten, and similar cases were also reported by Blackfan.<sup>4</sup>

The preponderance of sensitivity to egg white in these congenitally sensitized infants can be assumed to be due to its consumption by the pregnant woman in relatively large amounts (often in a raw or partially cooked state), to its low molecular weight and to its low coefficient of digestibility.

Even more convincing than infants sensitive to egg are those young infants who react to nuts, fruits and

vegetables, which foods, by the farthest stretch of the imagination, could not be presumed to have been ingested by them.

In the paper written by Lyon<sup>14</sup> in 1928, which appeared shortly after my article on the influence of the antepartum diet on allergy in infancy, a case is described of an infant 3 weeks old in whom angioneurotic edema developed and at 6 weeks cutaneous reactions to corn and navy beans were positive. The mother gave negative cutaneous reactions. In his paper the author stressed only the possibility that these antigens had come through the breast milk. My interest was aroused by the case and, in subsequent correspondence, I learned from Dr. Lyon that the family lived in the inaccessible rural mountain regions of West Virginia. At times the natives live almost exclusively on corn bread and dried navy beans. He further stated that the mother of the patient subsisted on such a bizarre diet for the last ten weeks of her pregnancy; prior to that time she had partaken of a reasonably good diet. It seems doubtful that the infant could have been sensitized in so short a time from the minute amounts of foreign protein in the breast milk. The more plausible explanation, it seems to me, is that the infant was sensitized in utero.

Another point of interest is that the angioneurotic edema was more probably due to contact of the mother's hands than to the breast milk. This woman made her own corn bread and her hands may have been contaminated with the food proteins, which were thus brought in direct contact with the mammary glands and the infant's skin.

This remarkable case emphasizes the need for testing even young infants with food proteins other than egg, wheat and milk to which many investigators have limited themselves.

Intra-uterine sensitization by no means explains all the cases. Only 55 per cent of our infants gave evidence of such initiation of sensitivity. The remaining 45 per cent must have acquired food sensitivity after birth. Milk and wheat proteins are the early prime offenders. The studies of Schloss<sup>21</sup> so clearly demonstrate the mechanism of intestinal permeability to foods in malnourished and normal infants that the validity of this form of acquisition is unquestioned.

Analysis of a case of idiosyncrasy to milk cited by Talbot<sup>3</sup> can be used to exemplify the development of postnatal sensitization.

A healthy, exclusively breast fed baby at 8½ months of age was given one bottle of milk formula. This was not given again until three weeks later because the baby had an infection of the middle ear. After recovery the milk formula was tried again but refused by the baby. It was, therefore, fed to him by spoon, but he vomited it. Several further attempts were made to give milk or whey, but vomiting ensued each time. Breast feeding was resumed for one week and was tolerated. Subsequently, 1 ounce (30 cc.) of milk was put into 8 ounces (240 cc.) of cereal gruel and only one teaspoonful of this mixture was given. The baby shuddered and vomited, and within an hour his body was covered with an urticarial eruption. The child was put on goat's milk without further trouble. Six months later, cow's milk was resumed and tolerated.

The factors influencing this mode of sensitization are covered more fully in part II of this series<sup>22</sup> and cannot be gone into at greater length here.

Although so much stress has been laid on the dominance of sensitivity to egg, which we found in 67 per cent of our cases, this substance could not have been the cause of the allergic manifestation in the infants who were not receiving it in their diet. If egg is not the provocateur of an eczema in the very young and is merely indicative of a potential sensitivity, and if, at the same time, one finds positive reactions to environmental substances, then obviously the latter substances must be causally related to the eczema. Practically in all these cases there was multiple sensitivity (94 per cent). It has been thought that inhalants and contactants begin to play their role much later than foods, but we did not find it so in our patients under 1 year of age; as I have already noted, 53 per cent reacted to inhalants and contactants in addition to foods, and 6 per cent to pollens in addition.

In table 1 are listed some of the reactions obtained in these young infants. As will be noted in several instances, the inhalant-contactant group is the major offender even though reactions to foods are positive. The articles of Peck and Salomon,<sup>23</sup> Hopkins and Kesten,<sup>24</sup> Hill and Sulzberger<sup>25</sup> and others emphasize the

childhood, but it is only after the sixth year that the incidence of fixed hay fever becomes notable. It is well known that the major number of hay fever sufferers commence their symptoms after puberty, the second decade being the most vulnerable period. However, one cannot be too dogmatic about it, for our studies pertain to the middle Atlantic states, and it must be acknowledged that workers in the great Southwest believe that

TABLE 2.—Age of Onset and Duration of Various Syndromes Before Seen

	Age of Onset	Duration Before Seen for Allergy	Average Age of Patient when Seen for Allergy
Eczema.....	0.7 years (3 days-5½ yrs.)	1.8 years (1 wk.-11.9 mos.)	2.5 years
Asthma.....	3.6 years (2 mos.-13 yrs.)	3.6 years (0-14 years)	7.2 years
Hay fever....	7.9 years (9 mos.-13½ yrs.)	3.9 years (0-11 years)	11.8 years
Urticaria.....	4.4 years (5 mos.-14 yrs.)	2.3 years (1 mo.-1 year)	6.7 years

Age of onset in eczema-asthma cases: Eczema 0.6 year; asthma 3 yrs.

hay fever may start early in life.<sup>26</sup> Kahn reports that 10 per cent of his patients with hay fever are under 1 year, and in five cases he states that hay fever symptoms existed from birth.

The urticarias appear to jog along sporadically throughout childhood, and, when one recalls the 3 week old infant of Lyon, it is evident that no period is free from this syndrome.

It is of further interest to note (table 2) that the period between the age of onset and the time that medical attention is sought is shortest for eczema (1.8 years) and next in order comes urticaria (2.3 years); the longest periods elapse in the case of asthma and hay fever (3.6 years and 3.9 years respectively). Perhaps because eczema and urticaria are very troublesome and disfiguring patients are brought for treatment earlier than with asthma and hay fever. The latter conditions are difficult to diagnose and sometimes require several years of observation. They are frequently wrongly diagnosed

Chart 1.—Showing influence of the allergic syndrome on age of onset.

and treated as common colds, recurrent bronchitis, pneumonia or whooping cough.

The average age of the patient at the time of study is youngest for eczema and oldest for hay fever.

TABLE 1.—A Group of Cases in Infants Under 1 Year of Age Showing Multiplicity of Sensitivity

Case	Age, Months	Condition	Positive Reactions
1	3	Eczema	Egg, wheat, silk, and environmental substances
2	4½	Eczema	Egg, milk, vegetables
3	5	Eczema	Egg, milk, contactants
4	6	Eczema	Egg, milk
5	6	Eczema	Orange
6	7	Eczema	Egg, apple
7	7	Eczema	Egg, several vegetables, contactants
8	7	Eczema	Egg, contactants
9	9	Asthma	Egg, inhalants and pollens
10	10½	Eczema	Egg, pea, chicken feathers and cotton lintens

important role of environmental substances in the causation of eczema not only through direct contact of the skin but also from inhalation.

The reason that increasing numbers of reactions are being obtained must be attributed to more extensive testing. Instead of limiting ourselves to egg, milk and wheat in these young infants, we tested them with practically all proteins, including direct tests with substances derived from the immediate environment of the infant. Thus we discovered not only immediate offenders but also potential ones.

#### NATURAL PROGRESS

The discussion thus far has pertained to those infants under 1 year of age. In chart 1 is shown the age of onset for the entire series of 250 children in relation to the major allergic syndromes.

From our experience, it would seem that eczema starts earliest; very few, if any, new eczemas start after the sixth year. While asthma may have its onset at any time during childhood, very few cases appear to start in the first year; the largest number of asthmatic children date their first definite symptoms of dyspnea from the third to the fourth year. The story of hay fever is different; an occasional case may occur in early

23. Peck, S. M., and Salomon, Gustav: Eczema of Infancy and Childhood: I. Contacts as Etiologic Agents, with Particular Reference to Feathers, *Am. J. Dis. Child.* 46: 1308-1328 (Dec.) 1933.

The progress of the allergic conditions is interestingly delineated in charts 2 and 3. Here is shown the distribution of the allergic conditions among 250 children (chart 2) and among 315 adult allergic antecedents

Chart 2.—Distribution of major syndromes among 250 allergic children either alone or combined with other syndromes.

(chart 3). The majority of children (63.2 per cent) suffer from asthma, as do the majority of adults (53 per cent). Among the children, however, only 39.2 per

sufferers among the adult antecedents is indicative of the trend. As I have already indicated, urticaria occurs sporadically, and from my own experience presents no significant trend in relation to age. Pure asthma remains the major form of allergy both in childhood and in the adult period. A rather interesting observation to be derived from our studies is that, in those cases which manifest more than one syndrome, asthma is generally present, and, in view of the preponderance of pure asthmatic cases it would appear that phylogenetically the human subject resembles the guinea pig in that the lung structure seems to be the predominantly reactive organ.

An analysis of the reactivities that allergic children manifested is drawn in chart 4. A larger number of food reactions occur in the youngest patients, although environmental substances begin to show reactions in the young and after the second year almost parallel food reaction. This picture is somewhat different from the observations of Stuart and Farnham,<sup>16</sup> who in discussing the acquisition and loss of hypersensitiveness in early life conclude that hypersensitiveness to food proteins tends to be present at birth and is gradually lost during childhood, whereas hypersensitiveness to inhalant proteins tends to be acquired during the middle period of the first decade and is more resistant to change. Bullen,<sup>28</sup> as well, has found that inhalants play a more prominent role in childhood than is generally thought.

TABLE 3.—Allergic Sensitivity in Relation to the Allergic Manifestations

	Non-sensitive	Foods	Inhalants-Contactants	Pollens	Foods and Inhalants-Contactants	Foods and Pollens	Foods, Inhalants-Contactants, Pollens	Inhalants-Contactants, Pollens

cent of those with asthma have this syndrome alone, whereas 24 per cent have it in combination with other syndromes—in the majority of instances with eczema. The largest number of infants under 1 year have eczema that antedates the onset of asthma, as has been brought out by Schloss,<sup>20</sup> Peshkin<sup>27</sup> and others. Practically all the food sensitive asthmatic patients gave an early history of eczema.

With the adult antecedents, it is interesting to note that the majority of asthmatic patients have asthma alone and that there were no cases of combined eczema and asthma. This (absence of eczema-asthma group) of course does not present a true state of affairs for I as well as others have seen adult patients with this combination of syndromes.

But it is the general trend of the progress of allergy with which I am concerned here, and comparing the two charts one sees that eczema, which is a dominant syndrome in childhood, particularly in infancy and earliest childhood, plays a lesser role as age advances. Hay fever, on the other hand, is of comparatively little significance in early childhood—particularly in the middle Atlantic states—and shows a definite rise as the age of the patient increases. The large number of hay fever

Peshkin<sup>29</sup> emphasizes this point, asserting that 98 per cent of his allergic children were sensitive to one or more substances of the inhalant group. This would

Chart 3.—Distribution of major syndromes among 315 adult antecedents.

indicate that a child exhibiting protein sensitization nearly always is sensitive to some inhalant. Peshkin states that this observation is somewhat at variance with

27. Peshkin, M. M.: Asthma in Children: II. The Incidence and Significance of Eczema, Urticaria and Angioneurotic Edema, *Am. J. Dis. Child.* 32:862-871 (Dec.) 1926.

28. Bullen, S. S.: Some Observations on the Natural History of Asthma in Childhood, *New York State J. Med.* 29:545 (May 1) 1929.  
29. Peshkin, M. M.: Asthma in Children: I. Etiology, *Am. J. Dis. Child.* 31:763-814 (June) 1926.

the earlier views that food sensitization was more commonly met than any other group. From Australia comes further supporting evidence by Barlow,<sup>30</sup> who states that environment has been rather underestimated as a factor in determining sensitization. In childhood,

Chart 4.—Showing distribution of positive cutaneous reactions at the different ages: One hundred and nineteen patients reacted to foods, ninety-three to inhalants-contactants and forty-four to pollens.

the patient will often prove to be sensitive to food as well as to inhalant proteins, but only rarely are foods the main allergic factors.

In our series, pollens began to cause reactions at a later period than either foods or inhalants and contactants.

A further analysis of the distribution of these various reacting substances is presented in chart 5.

The relation that the allergenic sensitivity bears to the allergic manifestations is summarized in table 3. Among the patients with eczema, 40 per cent react to foods alone and 5.7 per cent to epidermals alone, the remainder reacting to a combination of foods, inhalants, contactants and pollens. With asthma, 11.5 per cent react to foods alone and a higher percentage (22.9) to inhalants. With the eczema-asthma group, 2.8 per cent react to foods alone, 5.6 per cent to inhalants alone and the overwhelming majority to various combinations. It is noteworthy that among patients with hay fever 93.3 per cent react to pollens alone, and 6.7 per cent to pollens and inhalants, which suggests that certain patients with hay fever, even in childhood, will not do well if tested and treated for pollen sensitivities alone.

These observations show clearly that, except for the youngest patients with eczema, who may be preponderantly sensitive to foods alone, the allergic patient must be suspected of being sensitive to multiple allergens in the various groups.

#### COMMENT

The varying criteria employed by different investigators make it difficult to compare our results with those of other students. For example, the fact that certain investigators limit themselves to the use of a few test substances whereas we have tested with all available proteins makes a comparison of results with respect to cutaneous reactivities meaningless.

Probably the greatest criticism that can be leveled against the present study, as well as others of a similar nature, is the fact that children of varying ages have

been grouped together and conclusions have been drawn as representative of childhood. To be really valid, an adequate number of cases at each age level should be studied. Each case should be studied with as many test materials as possible. Since such studies entail a vast amount of detail, and since the cases available to any single investigator are limited, it may be useful to collect material from several clinics. Conclusions drawn from data thus collected and properly collated would be of great value.

Failing such an ideal study it is useful at times to take stock of available observations, which may yield helpful suggestions.

That allergy can actually be manifested in the newborn and be present in the young infant under 1 year is of significance, for it must arouse in the physician a much keener appreciation for the need of early diagnosis. When one realizes that a large percentage of allergic adults first manifested symptoms in childhood, it is apparent that improperly diagnosed and untreated cases may persist for unnecessarily long periods.

That eczema is a forerunner of asthma in many instances is a fact that is known to all interested in this field and should become common knowledge to all physicians. More dermatologists today have an awakened interest in this subject and no longer regard these endermal manifestations as topical diseases but stress their constitutional nature (Hopkins and Kesten, Hill and Sulzberger, Peck and Salomon and others). It is true that infantile eczema must be treated locally,

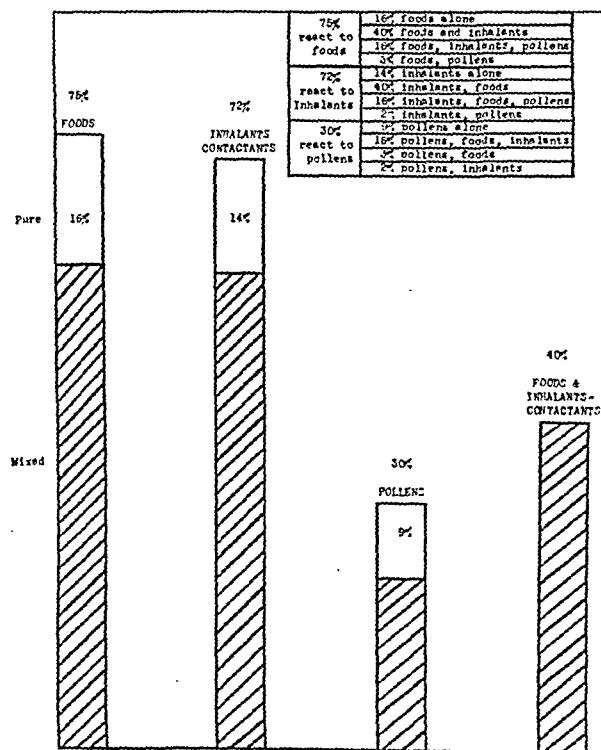

Chart 5.—Showing general distribution of positive cutaneous reactions.

but it is equally true that, unless the underlying reasons for the existence of the eczema are determined, recurrences and exacerbations must surely follow, and possibly the development of asthma.

One must also be alert to the early beginnings of respiratory allergy. In many instances, it is ushered in not by previous eczema but by recurrent episodes of

<sup>30</sup> Barlow, D. L.: Asthma in Children, *M. J. Australia* 1:4 (Jan. 1) 1938.

sneezing, lacrimation, rhinitis and attacks of coughing. The early episodes will perforce be treated symptomatically, but if these recur time and again the more serious allergic manifestations—asthma and hay fever—must be thought of.

Valid objections may be raised to the limited approach taken in the analysis of these cases, but I might state here that a discussion of all the other phases of the study of these cases relative to anamnestic data, eosinophil studies, the criteria employed in diagnosis, the psychogenic factors and the unreliability of the cutaneous test would have led us too far afield. These phases will be considered elsewhere. It will also be noted that I have made no attempt to discuss the intriguing question of prognosis for the reason that I was not concerned here with the progress of the individual case.

#### CONCLUSIONS

No dogmatic conclusions can be drawn with respect to the onset and progress of allergic syndromes in childhood. This is due to the fact that our knowledge of the underlying mechanism of allergy is still far from complete.

It is apparent that allergy may start at an extremely early age. The newborn period is signally free, with the rare exception of an occasional instance of passive sensitization acquired in utero.

Eczema is the prevailing allergic syndrome in infants under 1 year of age, and foods are the prevailing reacting substance. Though food sensitivities were found in 100 per cent of our patients under 1 year of age, they are nevertheless not always the sole cause of the allergic syndrome. The allergic eczemas in many instances (59 per cent) are shown to be due largely to contact with environmental substances to which these same infants react.

Infants who react to egg and other food proteins which they have never ingested have most probably been actively sensitized in utero. The early allergic manifestations may be invoked by a passage of these substances through the breast milk in infants previously sensitized in utero. On the other hand, such potential sensitivities may cause allergic reactions when these foods are eventually added to the diet in the latter part of the first year.

The age of onset of eczema is considerably earlier than that of asthma and, in many instances, it is the forerunner of asthma.

After early infancy, asthma becomes the prevailing allergic syndrome, and wherever there is a multiplicity of syndromes asthma is generally one of the complicating conditions. Asthma was also the dominant form in the allergic antecedents of the children studied. It appears, therefore, that the lung structure is phylogenetically predisposed to sensitization in the human species as it is in the guinea pig.

Hay fever is not of great significance in early infancy in the middle Atlantic states. It comes to the fore in the latter part of the first decade and becomes a prominent syndrome in the second decade of life.

Urticaria at all times remains sporadic and shows no particular age alinement.

Though food sensitivities play a very important role in the allergy of childhood, inhalants and contactants play an equally important one. Throughout infancy and childhood reactions to foods and inhalants and contactants run a parallel course. There are many infants and children who react to pollens who do not suffer

from hay fever. The pollens may be contributing factors in the eczema or asthma, or they may indicate potential sensitivities which eventually cause the onset of hay fever.

The preponderance of multiple reactivities would suggest that specific therapeutic measures may fail if all the offending factors are not taken into account.

The onset of allergy can in a measure be prevented through control of the diet of the pregnant woman and of the young infant. Cognizance of the important role that environmental inhalant substances play in earliest infancy too must lead to prophylactic measures.

The progress of allergy can be interrupted by early diagnosis of the interrelated syndromes and reduction of contact with inciting substances.

It is true that in the present state of our knowledge it is difficult actively to engage the interest of the physician who is unprepared by training and equipment in this subject, which appears to be complicated by so many factors and which from many reports seems to yield but few satisfactory results.

The time must soon arrive, however, when the salient facts, gleaned from the maze of work that is being carried on, will be separated from the chaff and formulated into broad principles that can be more readily applied in general everyday practice.

50 East Seventy-Eighth Street.

#### ABSTRACT OF DISCUSSION

DR. MILTON B. COHEN, Cleveland: It is interesting to me, an allergist interested in pediatrics, to hear a paper by Dr. Ratner, a pediatrician interested in allergy, and to find that there is no essential disagreement in our points of view. This arises, I believe, from the fact that as clinicians study any disease, no matter what discipline they bring to the study originally, they ultimately arrive at certain general conclusions which are in agreement. This paper calls attention to the fact that the pediatrician is the one who is going to see the earliest manifestations of allergy and going to see the child at a time when certain destructive processes produced by long-standing disease may be prevented. It is very important that one think of allergy not as asthma or hay fever or allergic rhinitis or urticaria, but as a clinical condition which may manifest itself anywhere in the child economy and that one follow it wherever it goes and treat it accordingly. Therefore, it doesn't make a great deal of difference whether in your practice the statistics vary slightly from Dr. Ratner's or whether in my practice they do. The important thing is that this condition should be recognized early. It can be recognized early and, if it is managed early, many of the changes which occur in adult life may be avoided.

DR. TELL NELSON, Evanston, Ill.: I am in accord with what Dr. Ratner has pointed out. That allergy is common in infancy and childhood cannot be discounted. But, unfortunately, it is often minimized and frequently overlooked. Dr. Ratner stated that between 50 and 60 per cent of adults date their allergy from early childhood. In a series compiled some years ago, I found that in 66 per cent of all my cases the allergic symptoms had started before 20 years of age. It is interesting that in the first decade twice as many males develop allergic manifestations as females. In this study I took into consideration eczema, asthma and hay fever, including in hay fever the hypersensitive rhinitis type of manifestation. What the difference in sex means, I am not ready to state. I was happy to hear Dr. Ratner stress the inhalant factors in addition to the foods in infants and children. I find inhalants as important in early infancy as foods. Dr. Ratner also mentioned the finding of hay fever, of pollen sensitivity, as starting early in life and being very gradual, beginning to manifest itself in a fairly good proportion along about 6 years of age. He stated that this was probably due to the fact that their cases may differ somewhat because of location. In the Middle

West I find a goodly proportion of my patients definitely pollen sensitive quite early in life. I can't give exact figures, but in my own practice and in the clinics a large percentage of children manifest definite hay fever symptoms at 2 and 3 years of age. It is only by careful study of children who manifest frank allergic symptoms and the recognition of those children who manifest early stigmas of the allergic constitution that it will be possible to manage this type of individual better and avoid the trouble which will appear later in life.

## RENAL TUBERCULOSIS: PROGNOSIS FOLLOWING NEPHRECTOMY

BASED ON PREOPERATIVE OBSERVATIONS IN THE  
"GOOD" KIDNEY

JOHN L. EMMETT, M.D.

AND

JOHN M. KIBLER, M.D.

Fellow in Urology, the Mayo Foundation  
ROCHESTER, MINN.

The indications for nephrectomy in the presence of renal tuberculosis are commonly discussed. Opinion on this subject is unsettled, partly because of lack of agreement concerning the pathogenesis of the disease. One group of investigators, following Medlar's teaching, feels that renal tuberculosis always begins with bilateral involvement, while another group maintains that it begins in most cases as a unilateral infection. This argument has academic interest, but the patient desires only to be relieved of his symptoms and to have his life prolonged.

Generally speaking, four clinical methods can be employed to investigate a kidney in the presence of this disease: (1) urography, (2) determination of the amount of pus present in the specimen of urine obtained by ureteral catheterization, (3) inoculation of guinea pigs with the specimen of urine obtained by ureteral catheterization, and (4) an attempt to demonstrate the bacilli of tuberculosis in stained smears of the specimen of urine obtained by ureteral catheterization. Past experience has taught that none of these tests are infallible; therefore it may be said that in renal tuberculosis it is impossible to prove clinically that one kidney is free of infection. Nevertheless, all the tests are valuable and the question today is how many of these tests should be employed and the finding of what manifestations relative to the so-called uninvolved kidney should be insisted on before subjecting the patient to removal of the involved kidney. It would seem that the most practical approach to this problem would be to study the postoperative results in a large group of cases of renal tuberculosis in which nephrectomy had been performed. By grouping these cases according to the method of investigation and according to the observations obtained in relation to the so-called uninvolved kidney, a comparative analysis of the operative results should be possible and should help to solve this problem. We have attempted to carry out this plan of study in the analysis of a series of cases and trust that further analysis of the results will be of some practical value. For brevity we shall refer in this paper to the diseased kidney that was removed at operation as the "bad"

kidney, while the so-called uninvolved kidney will be spoken of as the "good" kidney. Also for brevity it will be said herein that "guinea pigs were positive" or "negative" rather than that "the result of inoculation of guinea pigs was positive" or "negative."

We have studied the records of 1,131 consecutive patients on whom nephrectomy was performed for renal tuberculosis at the Mayo Clinic between the years 1912 and 1932 inclusive. The results in these cases have been studied from the standpoint of the observations obtained in the clinical investigation of the good kidney prior to operation. No attention has been paid to the condition of the bad kidney which was removed or to the type of surgical technic employed. Pathologic conditions outside the urinary tract, both tuberculous and nontuberculous, have been disregarded as they are probably evenly distributed among the artificial groups we have made for comparison and would therefore not seriously affect the analysis. No patients were studied who were operated on after 1932, in order that all cases might be studied from the standpoint of at least five year survival. Of the 1,131 patients, 453 were known to be dead. To the remaining 678 patients letters of inquiry were sent, answers to which were received in more than 70 per cent of cases. In many of the cases in which replies were not received, as well as in many of those in which the patients were known to be dead, the records contained previous correspondence, including replies to questionnaires of previous years, which supplied considerable information. In our letter of inquiry we asked the patient if, and to what extent, his vesical trouble had improved since his operation, and further we requested him to state the number of times he found it necessary to void both day and night and the amount of pain or burning that accompanied urination. Inquiry also was made as to the state of his general health. From the information obtained, the following classification of results was formulated:

1. Patients dead. Information on this group also included the date of death.
2. Patients cured. Only those patients who were entirely free of all vesical symptoms were included in this group.
3. Patients improved. These were patients whose vesical symptoms had improved since operation but vesical symptoms of some kind, even though slight, still persisted. The group included patients whose bladders were contracted and whose frequency of urination persisted in spite of microscopically negative urine. It also probably included a generous number of patients in examination of whom, if cystoscopy was done, pathologic change would not be found.
4. Patients unimproved. This group included those whose vesical symptoms were not improved or became worse.
5. Condition unknown. These were patients who at the time of writing this report we knew were still alive but we were unable to ascertain their condition.

Regarding the patients who were dead, no attempt was made to study the cause of death, as such reports are so unreliable in most cases as to be practically valueless from a statistical standpoint. Although we are sure that a large number of these patients died from causes unrelated to their renal tuberculosis, we feel that they were well enough distributed throughout the various groups in this study as not seriously to affect the comparative results. In other reliable reports in the literature are estimates of the mortality that may be expected from tuberculosis elsewhere than in the urinary tract, so that this phase was not studied in our

• From the Section on Urology, the Mayo Clinic.  
Read before the Section on Urology at the Eighty-Ninth Annual Session of the American Medical Association, San Francisco, June 16, 1938.

series of cases. All percentages recorded in the accompanying tables were based on the number of traced patients as denoted in each table.

A word should be said about the terms "cured" and "improved." It would seem that, if a patient is in good health from ten to twenty years after operation but still complains of moderate frequency of urination, the assumption would be justified that the tuberculous process had been eradicated and the patient probably cured. This interpretation has been used in most statistical papers on renal tuberculosis. We have preferred, however, to list such patients as "improved" only, reserving the term "cured" for complete absence of symptoms referable to the bladder. For this reason, in a comparison of our tables with those of some other authors, a total of our cured and improved patients would more nearly correspond to "patients well" in their reports.

There seems to be little if any preference of the disease for either side, as the right kidney was removed in 602 cases and the left in 529 cases.

#### AGE

The average age of the patients operated on varied little from year to year during the twenty years of the study. We felt that it would be of interest to determine whether there was any great variation in postoperative results among patients of the various age groups. Table 1 indicates that there was essentially no difference. Although results obtained with patients of the second and seventh decades differed somewhat from the results obtained with patients of the other decades, it must be borne in mind that the patients of these two decades who were traced were too few to yield accurate percentages. The youngest patient operated on was 8 years of age and the oldest 71 years of age.

20	227	106	175	76	66.3	44.7	25.7	44.7	4.6	7.9	1.1	0	2.3	2.7

As has been stated previously, the primary object of this study was to learn the results of nephrectomy from the standpoint of the preoperative observations obtained in the investigation of the good kidney. We shall include also, however, regarding this rather large group of cases, a few general statistics that should be of especial interest to the student of this subject.

#### INCIDENCE

The number of cases in which nephrectomy has been performed at the clinic each year since 1912, for renal tuberculosis, indicates a definite reduction in the incidence of this disease. For instance, in the six years 1920 to 1925 inclusive an average of fifty-nine patients with renal tuberculosis were subjected to nephrectomy yearly, whereas in the six years from 1932 to 1937 inclusive the yearly average was only twenty-six. These figures are particularly significant when one considers that the average number of patients admitted to the clinic yearly from 1932 to 1937 inclusive was 9.3 per cent higher than in the six years 1920 to 1925 inclusive.

#### SEX

The disease affected almost twice as many males as females. Nephrectomy was performed on 724 males and on only 407 females (table 2). The most striking information obtained from this table, however, is the difference in the clinical results following operation in persons of the two sexes. That the disease is far more serious to the male is shown by the fact that in the study of ten year survivals almost twice as many males as females were dead, whereas the incidence of cure among females was strikingly higher than it was among males. The reason for these differences is not obvious but the rather common occurrence of associated genital tuberculosis in the male may be a factor.

#### POSTOPERATIVE RESULTS FROM THE STANDPOINT OF THE "GOOD KIDNEY"

In this part of the paper are reported matters pertaining to the primary purpose of the study, namely postoperative results from the points of view of the method of investigation applied to, and the clinical results

obtained from, the good kidney prior to operation. The patients were divided into four main groups as follows: Group 1, patients whose good kidney was not catheterized prior to operation. Group 2, patients whose good kidney was catheterized prior to operation, and microscopic examination of the centrifuged ureteral specimen of urine revealed either no pus cells or not more than three pus cells per high power field. Group 3, patients whose good kidney was catheterized prior to operation and microscopic examination of the ureteral specimen of urine revealed from three to ten pus cells per high power field. Group 4, patients whose good kidney was catheterized prior to operation and microscopic examination of the ureteral specimen of urine revealed more than ten pus cells per high power field. We have

the good kidney was carried out in 369 cases, or 76.4 per cent of the 483 cases in which operation was performed, whereas between 1920 and 1932 it was carried out in 604 cases, or 93.2 per cent of the 648 cases in which operation was performed. Inability to catheterize the ureter on the good side in the presence of extremely irritable or contracted bladders is another common reason for omission of catheterization.

Table 3 discloses that the mortality rate both five and ten years after operation was much greater in group 1 than it was in group 2 (the group in which the urine was microscopically negative). On the other hand, the mortality rate was about equal to that of groups 3 and 4. From the standpoint of patients cured the difference was not so striking, but there was still

10	931	753	302	40.1	275	36.5	107	14.2	29	3.9	40	5.3
15	666	513	262	51.1	174	33.9	51	9.9	12	2.3	14	2.8
20	333	251	150	59.7	79	31.5	14	5.6	2	0.8	6	2.4

compared these four groups of patients in table 3; no attention was paid to inoculation of guinea pigs or to acid-fast staining. The patients are compared as to postoperative results both five and ten years following operation. In group 1 there were 161 patients. The question may be asked as to why the good kidneys in these cases were not catheterized. The majority of cases in this group are those in which diagnosis was made and operation performed between 1912 and 1920, when cystoscopic instruments and technic had not reached the refinement that has been attained in the last twenty years. In many of these cases cystoscopic examination revealed thick pus exuding from the ureteral orifice on one side and clear urine spurting from the ureteral orifice on the other side; nephrectomy was carried out on the basis of this information only. For instance, in the series of cases in which operation was performed between 1912 and 1920, catheterization of

a much larger percentage of cures in group 2, as would be expected. There was a much higher percentage of cures in group 1 than in group 4, which can be explained by the fact that all the good kidneys in group 4 contained considerable amounts of pus, whereas in group 1 a large percentage of kidneys were no doubt secreting microscopically negative urine. One important point must not be overlooked, and that is that 20 per cent of the patients in group 4 (the group in which more than ten cells per high power field were found in the ureteral specimen of urine) were cured ten years after operation. Although the number of patients traced in this group was so small that the percentage had little statistical value, it nevertheless is significant and must be taken into consideration. This will be considered more fully later. When the results in these four groups are compared with the results obtained in the series as a whole, regardless of method of diagnosis

(table 4), the results in group 2 are seen to be considerably better than the average for the entire series.

In an effort to evaluate the importance of investigating the good kidney by inoculation of guinea pigs and acid-fast staining of the urine obtained by ureteral catheterization, group 2, 3 and 4 each was broken down into divisions A, B and C. Division A indicates that guinea pigs were not inoculated and that positive acid-fast stains were not obtained. Division B indicates that guinea pigs were inoculated but that the results were negative and that positive acid-fast stains were not obtained. Division C indicates that either inoculation of guinea pigs or acid-fast stains, or both, were positive. The results in these various divisions of cases are compared in tables 5, 6 and 7. We speak only of acid-fast

value as far as percentages are concerned because the number of cases in each of these divisions was small. However, the tables do present points of interest. The most striking observation is the exceedingly high mortality in division C of both groups. No patients in group 4 C were cured in either five or ten years, whereas two patients in group 3 C were reported cured after ten years. Also seven patients in group 4 A were reported cured after five years and four after ten years, while less than this in group 4 B were cured.

#### UROGRAPHY

Before any deductions are drawn from the foregoing data a word should be said concerning the evaluation of urograms in this condition. As the cases in this

\* Group 2, "good" kidney catheterized; microscopic examination of urine specimen contained from 0 to 3 leukocytes per high power field. A, no guinea pig inoculated, no positive acid-fast stains obtained. B, negative guinea pig, no positive acid-fast stains obtained. C, positive guinea pig or positive acid-fast stain obtained, or both positive.

TABLE 6.—Analysis of Results in Group 3, Based on Inoculation of Guinea Pigs and Demonstration of Bacilli of Tuberculosis by Stain of the Urine Obtained from the "Good" Kidney by Ureteral Catheterization

Years After Operation	Group*	Total Patients	Traced Patients	Patients Dead		Patients Living							
						Cured		Improved		Unimproved		Condition Unknown	
				Number	Per Cent of Traced	Number	Per Cent of Traced	Number	Per Cent of Traced	Number	Per Cent of Traced	Number	Per Cent of Traced
5	3 A	89	77	33	42.9	22	28.5	11	14.3	5	6.5	6	7.8
	3 B	17	16	6	37.6	7	43.8	1	6.3	2	1.3	0	0
	3 C	15	15	8	53.3	2	13.3	1	6.7	4	26.7	0	0
10	3 A	85	69	37	53.6	18	26.1	9	13.0	3	4.3	2	3.0
	3 B	8	8	2	25.3	4	50.0	1	12.5	1	12.5	0	0
	3 C	10	10	6	60.0	2	20.0	0	0	2	20.0	0	0

\* Group 3, "good" kidney catheterized; microscopic examination of urine specimen disclosed from 3 to 10 leukocytes per high power field. A, no guinea pig inoculated, no positive acid-fast stains obtained. B, negative guinea pig, no positive acid-fast stains obtained. C, positive guinea pig or positive acid-fast stain, or both positive.

stains that were positive, because we feel that a negative stain of a catheterized ureteral specimen of urine is of little significance. In table 5 the cases in group 2 (with microscopically negative urine from the good kidney) are considered from the point of view of inoculation of animals and of acid-fast staining. The striking observation is the extremely high mortality in the division in which either positive guinea pigs or positive stains, or both, were obtained (division C) as contrasted with the division in which inoculation of guinea pigs proved negative and positive acid-fast stains were not obtained (division B). The percentage of cures in division B is also markedly higher than that in division C. The percentage in division A (guinea pigs not inoculated and positive acid-fast stains not obtained), as would be expected, falls between those of the other two divisions.

Tables 6 and 7, comparing group 3, divisions A, B, C and group 4, divisions A, B, C are of no statistical

series were not studied later than 1932, few excretory urograms were made. Nearly all the urograms were retrograde pyelograms. In the entire series of cases these pyelograms were made of the good kidney in forty-five cases. Of these, thirty-eight were considered normal. Thirty-five of the patients who gave normal pyelograms were traced five years, at which time 30 per cent were dead and 40 per cent were reported as cured. These results are about the same as for the entire series of cases (table 4). There were, however, too few pyelograms to warrant any conclusion being drawn from their study.

#### COMMENT

What, then, can be deduced from the information derived from study of the comparative results in these various groups of cases, and in what way can it assist in the diagnosis and plan of treatment in renal tuber-

culosis? In the first place, to make a fairly accurate prognosis, catheterization of the good kidney, to determine the amount of pus being secreted, is imperative. A negative urine in such a case leads to a favorable prognosis and our statistical data indicate that the patient may expect approximately 43.5 per cent chance of a five year cure, a 65.2 per cent chance of being cured or improved in that period and only a 20.3 per cent chance of death within five years. If, in addition to this, inoculation of a guinea pig gives a negative result and a positive acid-fast stain is not obtained, his chance of dying within five years will drop to 13.3 per cent, his chance of a five year cure will be increased to 50.3 per cent, and his chance of being either cured or improved will increase to 75.2 per cent. On the other hand, if the guinea pig is positive, the patient's chance of dying within five years increases to 41.8 per cent and his chance of a five year cure drops to 21.8 per cent. These figures are dramatic and demonstrate that the results differ greatly in cases in which the urine from the good kidney is negative, depending on whether the guinea pig is positive or negative.

The question then arises Should a positive guinea pig corresponding to the good kidney, in spite of

guinea pig or the stain is positive, the prognosis is poor and it is questionable if operation is warranted. In such cases, no doubt, fairly advanced bilateral renal tuberculosis is present and the possibility of clinical improvement of the better of the two kidneys, following operation, certainly is questionable. If there is a small amount of pus, if guinea pigs and stains are negative, and if the excretory urogram is normal, the prognosis seems to be reasonably good and possibly surgical measures are worth the trial. This is especially true if there are not more than ten or fifteen pus cells per high power microscopic field in the centrifuged ureteral specimen of urine.

One might well ask whether this study sheds any light on the old arguments whether renal tuberculosis is essentially bilateral and whether healing ever takes place in renal tuberculosis. Comparing the groups and divisions (2 C, 3 C and 4 C), it is seen that in group 2 C there is a considerably higher percentage of five and ten year cures, in spite of the positive guinea pig. There are fewer in group 3 C but still a fair number, whereas in group 4 C there are no five or ten year cures. Group 4 C, including as it does the cases in which guinea pigs or stains were positive and a considerable amount of

\* Group 4, "good" kidney catheterized; microscopic examination of urine specimen disclosed more than 10 leukocytes per high power field. A, no guinea pig inoculated, no positive acid-fast stains obtained. B, negative guinea pig, no positive acid-fast stains obtained. C, positive guinea pig or positive acid-fast stains, or both positive.

absence of pus in the urine, be considered a contraindication to surgical operation? It must not be forgotten that 21.8 per cent of such patients were cured, that a total of 36.4 per cent were either cured or improved at the end of five years, and that 30 per cent were either cured or improved at the end of ten years. Certainly almost any one who had the disease would be willing to submit to operation if given a 30 to 36.4 per cent chance of improvement for from five to ten years. If other factors do not constitute contraindications to surgical operation, and if the excretory urogram of the good kidney is within normal limits, it seems to us that a positive guinea pig should by no means be considered a contraindication to surgical measures, although it would considerably alter the prognosis. The common procedure, therefore, of performing nephrectomy in such cases, without awaiting the report of inoculation of animals, would appear to be justified.

When pus is found in the catheterized specimen of urine from the good kidney, the problem is radically altered. Because of the small number of such cases in our series it is difficult to make as far-reaching statements as have been made concerning the cases in which the urine was microscopically negative. However, tables 6 and 7 suggest that if more than three pus cells per high power microscopic field are found and the

pus was present, no doubt represents advanced lesions which probably are those which Thomas would classify as destructive lesions. In these cases progress would be expected to be poor. The cured patients in group 2 C and group 3 C, however, are not so easily explained. No doubt the positive finding in some cases is owing to reflux of vesical urine up the ureter or is attributable to the catheter, as it is passed through the bladder, picking up bacteria and pus. However, certainly some of these must have been bona fide cases of bilateral renal tuberculosis. That the lesion in the kidney became quiescent or clinically healed seems probable, although of course a conclusion cannot be reached unless the kidney is examined microscopically.

Although what has been written here does not settle the academic argument, it does clarify the practical phase of the subject, which is the only one in which the patient is interested. We believe that on a basis of these figures, which are drawn from a relatively large group of cases, it should be possible for the physician to give his patient a fairly accurate prognosis after complete study of the good kidney, including urography. The estimate, of course, must be tempered by consideration of the general condition of the patient, the presence or absence of associated disease (whether tuberculous or otherwise) and the approximate length of time the disease has been in progress.

## ABSTRACT OF DISCUSSION

DR. JOHN R. HAND, Portland, Ore.: The authors should be commended for their effort to crystallize our knowledge of the basic facts on which the surgical indications for nephrectomy and the prognosis are based. They have suggested that the study should include urograms, analysis of the degree of pyuria, inoculation of guinea pigs and staining the specimens obtained by ureteral catheterization of the good kidney to detect acid-fast organisms. I would add determination of the comparative functional capacity of the good kidney. This would probably be of greatest value when the prognosis was poor, that is, when pyuria was present. The authors' analysis allows one to visualize four important pictures: 1. That of a kidney not excreting pus or acid-fast bacilli. The patient with this type may expect a 50 per cent chance of cure, a 75 per cent chance of improvement and a 13 per cent chance of death within five years. 2. That of a kidney not excreting pus but excreting acid-fast bacilli. There is an area of caseous necrosis in which acid-fast organisms are escaping through the tubules but in which a pyogenic reaction has not yet occurred at the papilla. The patient stands a 21 per cent chance of cure, a 36 per cent chance of improvement and a 41 per cent chance of death within five years. (These two pictures make one realize that the acid-fast bacilli obtained in the specimen from the good kidney are in most instances not due to contamination.) 3. That of "a good kidney" with a normal urogram. The patient stands a 40 per cent chance of cure and a 30 per cent chance of death within five years. This picture emphasizes that even when the urogram is normal, acid-fast organisms may be coming from the kidney. 4. That of a kidney in which caseous necrosis, ulceration and a pyogenic reaction are taking place at the renal papilla, allowing the excretion of pus. Whether or not this pyuria is accompanied by excretion of acid-fast bacilli, the prognosis is poor. This paper reflects credit not only on Drs. Emmett and Kibler but on the teamwork and skill of the clinicians and surgeons who made their exceptional results possible.

DR. FREDERICK LIEBERTHAL, Chicago: It is natural to assume that an early lesion in the good kidney may heal after the removal of the bad kidney. Instances of such healing have been reported in the literature. The authors do not say how long they carried on their follow-ups, and hence the accuracy of their statistics is to be questioned. When one considers that tuberculosis may run its course for decades or even a lifetime, that long remissions may occur and that renal tuberculosis affects mainly persons between 20 and 40, in other words persons who would under normal circumstances have a long life expectancy, it immediately becomes clear that follow-ups of five, ten or even twenty years are imperative if accurate conclusions are to be drawn as to the ultimate fate of the patient. I believe therefore that in this regard Drs. Emmett and Kibler have struck the keynote of the problem, for I am convinced that many of the errors in the literature concerning renal tuberculosis are due to the fact that the follow-ups were too short. In this series the turning point seemed to come in those cases in which the separated urine from the good kidney contained fewer than 3 pus cells per high power field. The question naturally arises as to the extent of the lesions in these cases. A cell count of lower than 10 per field when there is good renal function and the excretory urogram is normal denotes that the renal lesion is limited to a solitary caseous ulcer on one renal papilla which scarcely covers the summit of the papilla. The fact that such a minute solitary lesion in the good kidney reduces the chances of a five year improvement or cure after removal of the bad kidney to only 21 per cent is worthy of consideration. Today there is a great tendency to treat frankly unilateral renal tuberculosis conservatively. I believe that this study offers a prophecy of the disastrous results which may be expected when ten and twenty year follow-ups become available for such treatment.

DR. J. C. NEGLEY, Los Angeles: My experience includes seventeen years of work in a tuberculosis sanatorium and eighteen years of work in a large clinic. I realized after a number of years that when the so-called good kidney was not catheterized bilateral renal tuberculosis was undiagnosed in many cases. The close correlation between the development of renal tuberculosis in the remaining kidney and bilateral renal tuberculosis diagnosed at the first examination is worthy of

note. In a series of cases which I reported four years ago, tuberculosis developed in the remaining kidney in about 4.5 per cent of all the cases in which operation was performed. In about 10 per cent bilateral renal tuberculosis was observed at the first examination. In the Urologic Clinic renal tuberculosis in the remaining kidney developed in 12.5 per cent of the cases and bilateral involvement was present when the diagnosis was first made. I offer a very radical procedure, for which I have been criticized. For the past seventeen years at the Olive View Sanitarium it has been the custom to take two sets of pyelograms every time a patient of mine is examined. That is, I make bilateral pyelograms with catheters at or near the renal pelvis and immediately afterward a bilateral set with the catheters at or near the level of the bladder. In seventeen years I have had no disastrous results. No patient has died. I have had no more reaction than if I had catheterized but one side, and the fear, always present, of setting up acute miliary tuberculosis through the pyelovenous back flow has never materialized. In the authors' paper a great deal of emphasis has been placed on not catheterizing the good kidney. If the good kidney is not catheterized, how does one know whether it is a good kidney or a bad one? The cases reported are similar to those observed at a large urologic clinic. The patient comes because he has symptoms, generally directed to one side. One kidney is catheterized and removed, and then the patient leaves. Constant contact is not possible. In the tuberculosis sanatorium, however, patients are under control at all times. Repeated examinations are performed as they show symptoms or as their bladder urine shows pathologic changes. In a number of cases bilateral renal tuberculosis is diagnosed. Despite the fact that the procedure is radical, I do not consider any case of renal tuberculosis studied completely until two sets of bilateral pyelograms such as I have described have been made, plus a test for pus cells, smears and inoculation of guinea pigs.

DR. WILLIAM P. HERBST, Washington, D. C.: There are several interesting phases of this tuberculosis problem. One should not forget that whether the patient gets well or not depends on his resistance and that renal tuberculosis is not a local but a constitutional disease. Gilbert Thomas has emphasized this fact repeatedly. All patients who have had a nephrectomy for renal tuberculosis should be treated with sanatorium care for a year in order to give their generalized tuberculous process a chance to heal and to improve the end results from the standpoint of lowering the incidence of involvement of the remaining kidney. Natural resistance to tuberculous infection varies markedly. Not infrequently one sees a patient who refuses surgical intervention carrying on for ten years or more and yet having extensive, active bilateral involvement. Such observations justify conservative handling in the early stages and reemphasize the necessity of complete sanatorium rest after nephrectomy whenever it is economically possible.

DR. JOHN M. KIBLER, Rochester, Minn.: Dr. Negley asked how we could be sure that one kidney was good. The terms good and bad were used only in a relative manner and were defined rather arbitrarily at the beginning of the paper. By "bad" kidney we mean the more involved of the two kidneys; by "good" kidney we mean the uninvolved kidney or the less involved of the two kidneys. As to the making of repeated pyelograms of patients suffering with renal tuberculosis, it is our opinion that cystoscopic examination should be kept at an absolute minimum, as it is usually very painful to the patient and may produce actual harm. Dr. Braasch and I recently reviewed the last 100 consecutive cases of renal tuberculosis in which operation was performed at the Mayo Clinic (Emmett, J. L., and Braasch, W. F.: Has Excretory Urography Replaced Pyelography in the Diagnosis of Renal Tuberculosis? *J. Urol.* 40:15-23 [July] 1938). We found that the trend in diagnosis was definitely away from retrograde pyelograms. Most diagnoses were made on the basis of an excretory urogram and examination of the ureteral specimen of urine from the good kidney. In an effort to avoid unnecessary cystoscopic examinations, a group of urologists is beginning to advocate diagnosis by excretory urograms alone in most cases of renal tuberculosis. Whether late postoperative results by this method of diagnosis will justify its continuance time alone will tell.

THE CERVIX UTERI IN OBSTETRICS  
AND GYNECOLOGY

JOSEPH L. BAER, M.D.

CHICAGO

Recognition of the intimate relationship of obstetrics and gynecology has come a long way since male midwives were first admitted to the birth rooms and since Marion Sims laid the foundations for modern gynecology.

In the truly great teaching centers and in most important hospitals it has long since been recognized that obstetrics and gynecology are twin specialties and should be taught together and so far as possible practiced together. It is true that most obstetric patients are and should continue to be cared for by men in general practice. The general practitioner who does obstetric work should be gynecologically trained and able to evaluate the gynecologic problems of his patients.

The interlocking pathology and principles of treatment of the cervix uteri demonstrate this unity well. The cervix is not merely an appendage protruding into the vagina. It is a distinct structural and functional entity. Its disorders may be related to its role in obstetrics or gynecology or both. This concept is vital to intelligent treatment.

The cervix is the conic or cylindric termination of the uterus, usually 3 cm. long. Of this two thirds protrudes into the vagina, the portio vaginalis, and one third is the so-called supravaginal portion.

The anatomic landmarks between the cervix and the corpus uteri are the reflection of the vesico-uterine peritoneum, the level at which the uterine arteries branch and the narrowing of the lumen of the organ at the anatomic internal os.

The isthmus uteri or pars intermedia, formerly a debatable subdivision, is now accepted and identifiable. It is essentially the supravaginal portion of the cervix. It extends downward for about 8 mm. from the level of the "anatomic internal os" to a point where the lining of the canal becomes abruptly cervical in character, the "histologic internal os."

The structure of the cervix, unlike that of the muscular corpus uteri, contains little muscle but much connective and elastic tissue. It is comparatively firm and unyielding. The superior end, the isthmus, is more muscular like the corpus but somewhat softer. This gives it the effect of a double hinge, which permits of ready backward and forward displacement of the corpus in the pelvic cavity. Whoever practices obstetrics must be familiar with the remarkable softening of the zone between corpus and portio in early pregnancy, the "Hegar sign." Again in late pregnancy and labor there appears the striking phenomenon of formation of the "lower uterine segment," that thinned out zone between the contractile corpus and the dilating cervix. These alterations involve the same segment of the uterus, the isthmus uteri.

The cervical canal extends from the external os to the anatomic internal os, is narrowest at these two points, averaging 4 mm. in diameter, and is slightly spindle shaped, averaging 7 mm. transversely at its widest point. In the formation of the cervix the ante-

rior and posterior walls are the stoutest. This becomes striking on examination of the postpartum cervix, and after involution the canal is found to be much wider as a result of the yielding and overstretching of the lateral walls. Histologically the lining membrane of the cervix is characterized by the presence of mucus-secreting glands which point downward and toward the canal and by the absence of cilia. The mucosa of the isthmus resembles that of the corpus. It can be distinguished by the direction of the glands. Those of the corpus point downward and toward the cavity and those of the isthmus upward and away from the canal.

The most striking histologic fact in connection with the cervix deals with the changes at the external os. The forward and backward interplay between the cuboidal cervical mucosa and the squamous epithelium covering the portio, with the external os as the prize, begins in fetal life. At the seventh month the canal of the cervix is lined by squamous epithelium. At birth the endocervix has pushed back the squamous epithelium beyond the external os and onto the portio in approximately 30 per cent of female infants, the so-called congenital pseudo-erosion. Within the first year of life in most of these infants the squamous epithelium acquires the mastery and the external os becomes the dividing line. Again at puberty a secondary physiologic pseudo-erosion may occur, which likewise tends to recede. This struggle continues throughout life.

In adolescence and maturity the epithelium covering the portio is subjected to the hypersecretions of the cervix which accompany certain constitutional diseases and to the irritation of cervical discharges due to inflammation. In either case the squamous epithelium is macerated, and the red mucus-secreting endocervix advances to erosion, which may be small and superficial or huge, furrowed and even papillary. Lastly, the cervix which has been traumatized in labor heals with gaping, gradual eversion, ectropion and erosion.

Postmenopausal atrophy of the corpus and cervix uteri is effected by two distinct influences. Atrophy of the corpus and its endometrium results from disappearance of the ovarian stimulus. Diminished circulation produces gradual atrophy of the cervix but to a much smaller degree than the shrinkage of the corpus. The endocervix retains its mature form and function (vaginal lubrication), since the cervix is not under the direct influence of the ovarian stimulus.

Fertilization, pregnancy and labor proceed normally only when all the organs involved are normal in structure and function. For fertilization the cervix should point posteriorly at right angles to the vaginal axis. It should not descend to the level of the ischial spines. The portio vaginalis should be covered right up to the external os by the smooth squamous vaginal epithelium. The external os should be sufficiently patulous, the mucous secretion from the endocervical glands should be distinctly alkaline and the canal itself should be slightly spindle shaped, terminating 3 cm. above the external os at the narrow internal os. At the time of orgasm this structure dips into the pool of semen deposited in the posterior vaginal fornix, and its alkaline mucosa forms a pathway of escape for the spermatozoa from the deadly acid secretion of the vagina.

With the foregoing in mind, it is easy to understand that retroflexion, retroversion and prolapse may render fertilization difficult or impossible. This type of infer-

tility may be overcome by the intelligent selection and competent execution of a corrective operation. The conduct of the ensuing labor should be so contrived as to preserve the operative results previously achieved.

The persistence of congenital pseudo-erosion or the development of pseudo-erosion after puberty, the erosion produced by inflammatory destruction of the epithelium covering the portio and its replacement by the endocervical epithelium, cervical laceration in labor with resultant eversion and erosion formation, all act as more or less insurmountable barriers to fertilization.

Endocervicitis not infrequently converts the normal alkalinity to an acid cervical secretion repellant to the spermatozoa. An endocervicitis may be the starting point of a puerperal infection with its chain of sequelae.

Inflammatory erosions with or without endocervicitis are often associated with urinary disturbances and with low backache. Appropriate treatment of the cervical lesion often results in complete relief of such symptoms.

Stricture of the cervical canal at any level may be congenital but is usually acquired. When inflammatory, it is usually below or above the spindle-shaped dilated zone, single or multiple, or it may affect the external os, "conglutinatio orificii cervicis externi."

Strictures may result from the trauma of curettage or following abortion, and application of radium may produce them. For demonstration of strictures of the cervical canal on specimens the frontal section is better than the sagittal section, as this lays the canal open in its widest diameter.

Each of these manifold lesions presents a separate gynecologic problem which may be solved in various ways. If the point requires further emphasis, this interlocking of obstetric and gynecologic problems justifies the bald assertion that no one can be a competent obstetrician without adequate training in gynecology and its converse.

Symptomless retroflexion and retroversion require no treatment. To facilitate pregnancy, however, if the malposition of the uterus is not maintained by adhesions a properly fitted pessary, removed and replaced monthly, may be a definite aid toward pregnancy.

The adherent corpus uteri can sometimes be dislodged and erected under anesthesia. When this fails, surgical correction is indicated. Formerly the Gilliam suspension operation or one of its modifications was the method of choice. It is still reliable when properly executed. Two points are especially important in this procedure. The short arm of the double loop of round ligament should not be more than 3 cm. long, so that the fundus uteri will sit snugly against the abdominal wall, and the point of implantation of the ligaments into the abdominal wall should be 4 cm. above the symphysis. If the attachment is placed much lower and pregnancy occurs, the uterus sometimes fails to expand evenly in the vertical axis and either an abortion follows or the pregnancy develops entirely at the expense of the posterior wall of the uterus.

It may be entirely adequate in selected instances to rely on shortening of the uterosacral ligaments, radical advancement of the bladder and other methods of shortening the round ligaments.

Surgical cure of prolapse of the uterus with preservation of fertility continues to tax the ingenuity of operators. Correct treatment of the cervix is vital to success. If an unduly elongated portion of the cervix

is preserved, the operation for prolapse is usually doomed to failure. If the cervix is amputated too close to the internal os, subsequent pregnancy usually ends in abortion or immature labor.

The parametrial fixation operation<sup>1</sup> has assumed first place in popularity. The important steps are denudation of an area of the anterior vaginal wall proportional to the size of the existing cystocele, if any; dislodgment of the bladder; amputation of enough of the cervix to reduce the overall length of the uterus to 8 cm., of which from 2 to 3 cm. should be cervix; parametrial fixation anterior to the cervix, and reconstruction of pubovesicocervical fascia. The perineal body, if relaxed by previous delivery, must likewise be thoroughly reconstructed. Another procedure which can be carried out vaginally is the Halban-Porges operation.<sup>2</sup> Here again the cervix must be reduced to proper length and the anterior peritoneal reflection opened after the usual vaginal dissection and upward displacement of the bladder. The anterior flap of the peritoneal reflection which overlies the back wall of the bladder is now pulled into the vagina until it no longer advances. The fundus uteri is then sutured transversely against this anterior part of the peritoneum as close to the parieto-vesical angle as possible. The peritoneal opening is then closed, a strong reconstruction of the anterior vaginal wall is accomplished and the perineal body is reconstructed.

Formerly the treatment of ectropion and erosion consisted in repeated application of various chemicals aimed at the destruction of the misplaced cuboidal epithelium. It should be noted that in all instances of erosion islands of squamous epithelium remain in the zone of the lesion and aid in the rapid epithelization of the portio when the overlying encroaching tissue is destroyed.

The modern method of treatment for ectropion and erosion is complete destruction by the electrocautery, first carried out by Hunner<sup>3</sup> in 1906. Originally it was thought that radial destruction with preservation of the intervening epithelium was necessary. Long experience has demonstrated that complete destruction, until a black eschar is achieved, is entirely safe. This can be carried out as a single office procedure and requires no anesthesia, local or general. Similarly, endocervicitis can be cured or so completely subdued with the platinum loop electrocautery or the Cherry electrode or by electrocoagulation as to permit the return of normal secretory activity.

In fifteen years of office cauterization with the nasal tip cautery I have observed only two instances of late hemorrhage, both controlled by recauterizing, and only one instance of stricture.

Strictures resulting from any of the causes previously given must be treated by vigorous dilation, the best type of instrument being the graduated metal Hegar dilators.

When pregnancy has been established, the cervix becomes increasingly important. It is the living barricade and barrier. It locks the developing fetus and its protective fluid chamber within the corpus cavity. It absorbs the shock of impact which may accompany coitus. It accumulates the mucus which is no longer carried out with the menstrual flow and so provides an effective plug against bacterial invasion of the corpus cavity. If now the cervix is too short, whether congenitally or because of operative or traumatic destruc-

tion, or if previous trauma in labor has left it gaping widely, it is easy to understand how abortion may ensue.

Chronic infection of the cervix in the presence of pregnancy has heretofore received little attention. The fear of producing abortion has kept physicians from attempting any direct attack on the lesion. Yet Miller and his associates<sup>4</sup> reported in 1930 the treatment of erosion and endocervicitis in 2,000 cases by electrocauterization of the cervix and the canal. Their series was limited to patients up to the twenty-eighth week. The procedure always caused contractions at the time, but there was only one abortion which they felt was due to the cauterization. They reported no obstetric abnormality traceable to the cauterization, a marked decrease in puerperal morbidity, no sepsis and no recurrence of the erosion after delivery. Absence of any recurrence of erosion in 2,000 deliveries is difficult to understand. Aside from this question, however, the preservation of pregnancy and the removal by cautery of a direct source of uterine infection may prove to be a tremendous step in the reduction of maternal morbidity.

Passmore<sup>5</sup> confirmed these results in 1932. He found only sixty patients among 600 who required cauterization, twenty-four with severe and thirty-six with minor lesions.

Effacement of the cervix, that is, the shortening of the long axis and its eventual merging into the lower uterine segment, may begin weeks before the onset of labor. Dilatation of the external os usually follows the dilatation of the cervical canal. The external os may persist as a pinhole-sized os (conglutination) after the cervix is completely effaced and the lower uterine segment is well thinned out. This condition may simulate complete dilatation on rectal examination and may result in application of the forceps to the head, the blades being forced through the uterine cap with inevitable severe injury.

When the cervix has been lacerated in previous labor the external os is no longer a dimple or slit but is a widely gaping orifice bordered by more or less hypertrophied everted anterior and posterior lips, with scar tissue in the lateral angles. This type of multiparous cervix is responsible for precipitate labor, for extensive additional cervical lacerations if the patient is permitted to bear down before dilatation is complete and for incarceration of the edematous anterior lip between the head and the symphysis, which, unless released by upward dislodgment, may prevent delivery and result in necrosis or avulsion of the incarcerated cervix. In this connection it is interesting to note that there are seventeen recorded instances of spontaneous annular amputation of the cervix in labor.

The issue of rectal versus vaginal examination in the conduct of labor should not exist. A single vaginal examination properly carried out either in the home or at the hospital is no menace to the safety of the mother and is the only way in which the physician of average experience can orient himself as to all the accessible factors involved in the delivery. Subsequently the rectal approach will tell the story of the disappearing cervix and confirm the level of the head. Further vaginal examinations may be done only for special indications.

Inspection of the cervix immediately after delivery reveals a massive organ hanging loosely in the upper

part of the vagina. The anterior and posterior segments are heavy, while the lateral zones are markedly thinned out. Lacerations when present are usually in the thin lateral walls of the cervix. The distance from the external os to the top of the vagina at this time is approximately 10 cm. A tear of 2 cm. in the lateral zone will, when involution is completed, be nothing more than a physiologic nick at the external os. Moreover, attempted suture of these thin edges is usually only a gesture. The patient in whom labor has progressed spontaneously and normally to complete effacement and dilatation, with subsequent advance of the head to the pelvic floor, rarely sustains a major injury of the cervix. Major injuries should be repaired promptly.

Danforth<sup>6</sup> reported the results of immediate inspection of 904 cervixes after delivery, excluding instances of bag induction, manual dilation and cesarean section. He found laceration in 102, sixty-nine primiparas and thirty-three multiparas. In fifty-eight the tear was less than 2 cm. and not sutured. In forty-four the tear was more than 2 cm. and in thirteen of these ranged from 3 to 5 cm. In these forty-four the tear was repaired, an incidence of only 4.5 per cent. This conforms to my own observation and practice. The inspection of the cervix as a routine after delivery is therefore superfluous in most instances and increases the risk of morbidity.

When injury is suspected because of operative procedures and inspection reveals a laceration exceeding 2 cm., repair should be carried out with loosely tied interrupted catgut sutures, the first being placed above the angle of the tear. For cervical bleeding one or more sutures may need to be tied more tightly. Repair of old cervical injuries at the time of subsequent delivery is not advisable. The risk of creating atri of infection is greater than the alleged advantage of sparing the patient a subsequent hospitalization.

Massive edema of the postpartum cervix has been reported many times. It must be differentiated from prolapse and inversion of the uterus. With bed rest and nonintervention the edema disappears in from ten days to three months.

Operative correction of cervical pathologic conditions varies with the lesion and the desired objective. Certain underlying principles may be enunciated. Simple birth injuries which are symptomless and are not accompanied by inflammatory changes require no treatment. If the patient is to retain her childbearing capacity, birth injuries requiring attention must be repaired in such manner as to avoid undue foreshortening of the cervix. If this is not an objective, other types of repair are available in which preservation of the proper length of the cervix and endocervix is no longer necessary. If the lesion is essentially the result of inflammatory changes with the development of multiple cysts and florid erosions, the cautery is adequate. It has completely displaced the Schroeder operation in my practice. For deep laceration with heavy scar formation, excision and approximation are indicated. If there is gross involvement of the endocervix as well as multiple cyst formation on the portio, the Sturmdorf operation—cone-shaped excision with utilization of the portio as a new lining for the canal—is excellent. For simple hypertrophy and elongation, low or high amputation is

4. Miller, H. A.; Martinez, D. B., and Hodgdon, M. E.: *Pennsylvania M. J.* 34: 708 (July) 1931.

6. Danforth, W. C.: *Am. J. Obst. & Gynec.* 15: 505 (April) 1928.

selected in accordance with the patient's wishes concerning pregnancy.

Each of these operative procedures is of the nature of a plastic surgical measure and calls for a nice sense of proportion and fit to accomplish a satisfactory end result. Still the selection of the appropriate operation is more important than extreme dexterity in its execution. The sound judgment of the trained "gynecician" is worth more to the patient than a cosmetic stub of cervix which will no longer protect pregnancy.

In the actual technic several points are important. Interrupted sutures are preferable to continuous or lock stitch sutures. They should be placed approximately 1 cm. apart and should be tied for apposition only. The suture material should be well chromicized no. 2 catgut. Occasional late hemorrhage has influenced many operators to utilize silkworm gut for the deep sutures in this kind of work. Tested catgut serves equally well and obviates the necessity for subsequent removal.

Benign tumors of the cervix, though infrequent, are usually fibromyomas. The accepted treatment is enucleation. In this connection a word of caution is advisable. Many patients with this type of growth are anemic because of protracted menstrual bleeding, with resultant lowered resistance to infection. The cervix is richly supplied with lymphatic vessels which drain into the broad ligaments. Death from sepsis may follow simple enucleation of such a tumor of the cervix. The patient should be prepared by a preliminary blood transfusion, and the field of operation should receive the most scrupulous preoperative preparation.

Carcinoma of the cervix holds first rank among all the obstetric and gynecologic causes of death. Hinselmann's<sup>7</sup> colposcope was devised to reveal tiny lesions of the cervix which might be incipient carcinoma and promptly curable. Schiller's iodine test<sup>8</sup> was aimed at the same objective. Each of these devices, to be effective, must be used as a routine, with biopsy of any suspicious areas. When the microscopic picture is clear-cut the lesion is usually one which should have aroused suspicion without either one of these aids. Other specimens, studied because they do not take up iodine, may show what Schiller called the preinvasive stage of carcinoma. Unfortunately this classification is not generally accepted by pathologists. I have found the colposcope unnecessary and the iodine test inadequate.

For the cure of carcinoma of the cervix the old issue of surgical measures versus irradiation scarcely exists any longer. Treatment with radium or roentgen rays or both has almost completely displaced surgical methods in the hands of the most experienced specialists here and abroad. Choice of treatment based on types of cells—that is, whether they are radioresistant or radio-sensitive—has been found fallacious with both types so often that type is really no longer a criterion.

Clinically, if the lesion is truly incipient with no detectable involvement of the deeper part of the cervix or the parametrium, hysterectomy followed by irradiation may still be justifiable.

The menace of the cervical stump after subtotal hysterectomy has been a source of some concern and an argument in favor of routine total hysterectomy. The Mayos<sup>9</sup> have regarded it as a potential focus of infection resulting in keratitis, iritis and arthritis of the small joints. If this were so, although atrophy is the common fate of the stump, the source of infection could readily be eradicated by vigorous use of the cautery.

Masson<sup>10</sup> reported ninety-nine instances of carcinoma in twenty years at the Mayo Clinic and expressed advocacy of total hysterectomy as a routine. He reported a mortality of 1.2 per cent among 3,085 subtotal hysterectomies and of 1.8 per cent among 1,588 total hysterectomies. He stated that this increased mortality was negligible. Actually, however, it was a 50 per cent increase. It means that if all the subtotal operations had been total there would have been fifty-five deaths instead of thirty-seven. Polak culled only 256 cases from the world literature up to 1920, and it is to be doubted whether this extremely low incidence of carcinoma of the stump justifies the increased mortality almost certain to result from widespread indulgence in total hysterectomy as a routine.

It has been my aim throughout this brief analysis to convey the picture of a structure which, though a part of the uterus, is as distinct from it in function, pathology and treatment as the hypophysis is from the brain. The full significance of this picture is best understood when viewed through a binocular, one side labeled obstetrics and the other gynecology.

104 South Michigan Avenue.

#### ABSTRACT OF DISCUSSION

DR. EDWARD A. SCHUMANN, Philadelphia: I shall confine myself to one or two points of Dr. Baer's paper. The management of the old injured, infected and lacerated cervix has undergone a continuous change during the past thirty-five years. At the beginning of this period the methods for the relief of this lesion consisted in the deep, widespread Schroeder amputation or the entirely inadequate Emmett trachelorrhaphy, leaving a canal of presumably infected glandular tissues. These procedures were superseded by the Sturmdorf operation, and recently since the appearance of the electric conization knife I have found it adequate to abandon all operations for repair of the lacerated cervix and to depend for its relief on a wider or lesser excision of the tissue with the electric knife. The deal of nonsense which has been spoken and penned about the dangers of vaginal examination is most unfortunate and unbelievable. This whole matter has been so misunderstood, in my opinion, that Dr. Baer's statement that "a single vaginal examination, properly conducted, causes no harm and is no menace to the parturient woman" was delightful. His second statement was to the effect that routine observation of the cervix after delivery is not necessary. For ten years I have followed and observed every cervix of every parturient woman, and they presented every degree of laceration. Those presenting any degree at all were subjected to immediate repair. Gradually I found that but little good was done by this procedure, and while I did not find any increase in morbidity as a result of it, it has been almost entirely abandoned by clinicians unless some indication has rendered such observation important. With regard to the effect of chronic cervicitis and endocervicitis with leukorrhea on the production of puerperal morbidity, I am considerably interested. My associates and I are now conducting a series of observations on this matter in an attempt to prove our impression that puerperal morbidity is not enhanced thereby. Another point of Dr. Baer's that I wish to applaud is that the colposcope

7. Hinselmann, H.: *Zentralbl. f. Gynäk.* 51:901, 1927.

8. Schiller's iodine test: A. Clean cervix and inspect for (1) color of mucous membrane, (2) presence and sites of leukoplakia, (3) presence of erosions and (4) color of eroded areas. B. Bathe cervix for one minute in a solution made of 1 part tincture of iodine, 2 parts potassium iodide and 300 parts distilled water and inspect for (1) normal epithelium (is pink; turns mahogany brown), (2) normal erosion (is pink or red; remains pink or red), (3) carcinomatous epithelium (may be pink or white; turns pearly white) and (4) connective tissue (is pink; remains pink). C. A white patch is suspicious and must be examined histologically. It may be (1) carcinoma, (2) syphilis, (3) hyperkeratosis or (4) a scar.

10. Masson, J. C.: *Am. J. Obst. & Gynec.* 14:486 (Oct.) 1927.

is unnecessary and the Schiller test inadequate. I should like also to thank Dr. Baer for two statements he did not make. He did not call the cervix the "tonsil of the uterus" and he did not ascribe to this purely connective tissue substance with its thin layer of mucosa all the ills to which the possessor of a cervix is susceptible.

DR. GEORGE W. KOSMAK, New York: Dr. Baer called attention to the importance of the cervix in pregnancy. Although, as he states, it is a part of the uterus, there is a distinct difference in its physiology and pathology. I feel that in many cases insufficient attention is given to this structure when malignancy has been excluded. Chronic inflammations of the cervix, however, give rise to a multitude of symptoms the etiology of which may not be recognized as residing in this organ but which frequently call for radical rather than palliative measures, such as local applications and linear cauterization. I believe the latter has been much abused and that it is applicable only for superficial lesions, such as the so-called erosions of the vaginal portion. Deep seated infections of the canal are not satisfactorily eliminated, and if deeper cauterization is required the resultant scar formation is undesirable. The removal of a conical mass of cervical tissue with the electrocautery, as developed by Hyams and others, is satisfactory but requires special aptitude and skill. I have had excellent results from the Sturmdorf procedure, and subsequent pregnancy is rarely interfered with. The behavior of the diseased cervix in pregnancy may be given further consideration. The polypoid erosions may undergo development in early pregnancy and the resultant bleeding, especially after coitus, leads to the diagnosis of an impending or inevitable abortion, with later resort to curettage. In every case of bleeding during this period, visual inspection of the cervix is demanded and the bleeding can frequently be checked with the platinum loop brought only to a dull red heat. A white heated point usually increases the bleeding. The treatment can be repeated at intervals of from seven to ten days, supplemented with appropriate suppositories, tampons and douches. I have never seen abortions follow this procedure. Bleeding from the cervix in the later months of pregnancy may simulate placenta praevia: again visual inspection is demanded but local treatment is less satisfactory. Naturally, placenta praevia must be definitely excluded, which is not always possible, particularly in the marginal or lateral types, as a cervix previously diseased is apt to undergo much earlier softening. Dr. Baer questions the advisability of immediate repair in the milder degrees of lacerations and with this I would agree, as there is more danger of local infection and possible interference with lochial drainage. Therefore the apparent depth of a tear is of less importance as a deciding factor for repair than hemorrhage.

DR. GOODRICH C. SCHAUFFLER, Portland, Ore.: I thank Dr. Baer for his scholarly and sound presentation. Ten years ago Albert Mathieu and I made a survey of everything in the literature in relation to the caustic and cautery treatment of the endocervix. We found that there occurred an interesting cycle. In 1840 interest in the use of caustics and the cautery on the endocervix began to rise; from that time on there were increasing case reports in the literature, coming to a peak in about forty years (1880). A subsequent peak was reached several years later by the incidence of stasis, cervical occlusion and difficult labor following these treatments. These were simply as reported in the literature and may not represent the true condition; but in view of the modern tendency to radical, so-called office procedures on the endocervix—conization, cauterization, deep really surgical procedures—I call attention to this historical cycle for what it is worth. I was interested in Dr. Baer's presentation of the mode of growth of the epithelium, the cuboidal epithelium, growing down from the uterus and invading the portio vaginalis. A slide from the genitalia of a stillborn fetus shows the vagina and the endocervix with the usual roles of "harbors of infection" definitely reversed. There is a smooth endocervix with practically no cervical glands. The stratified epithelium is still high in the cervix and the vagina itself is rugose, cryptiform and poorly drained. I call attention to this in relation to the infectivity of the immature cervix, which I believe is practically noninfectible from the point of view of the glandular structure involved.

## TREATMENT OF PREERUPTIVE MEASLES WITH CONVA- LESCENT SERUM

JEROME L. KOHN, M.D.

IRVING F. KLEIN, M.D.

AND

HERMAN SCHWARZ, M.D.

NEW YORK

It has been established that measles convalescent serum will prevent or modify measles in children intimately exposed to it if a sufficient amount of this serum is given intramuscularly by the fifth day after exposure. Sometimes this is effective up to the eighth day after exposure. The efficiency of the prophylaxis has been confirmed by observations in large series of cases all over the world.<sup>1</sup>

Sporadic attempts also have been made to mitigate measles even after it has reached the active stage by administering convalescent serum before, during and after the appearance of the eruption. Most investigators<sup>1</sup> have stated that these attempts were unsuccessful.

It also has been reported by many authors<sup>2</sup> working on experimental virus disease that once a pathogenic virus has invaded the body cells it is impossible for a therapeutic serum to cause any beneficial effect. The etiologic agent of measles in the light of many studies is probably a virus.

In spite of the discouraging reports of these therapeutic efforts and of the skepticism shown that any serum will mitigate a virus disease once it has reached the active stage, we felt that another, more systematic, therapeutic attempt to give convalescent measles serum in the preeruptive stage would be justified. If effective, such therapy might lower the mortality of measles, occurring in the weak, debilitated infant or child or in persons who have just recovered from an infectious disease or those suffering from an acute or chronic disease.

### MATERIAL AND PROCEDURE

In the spring seasons of 1937 and 1938, children admitted to the Willard Parker Hospital in the preeruptive stage of measles were given varying amounts of convalescent serum. Children who were admitted for some other illness and in whom measles developed while they were in the ward were similarly treated. At the time of injection, definite Koplik spots were present in all patients and none of the children had previously received any measles convalescent serum. In all, twenty-four children were so treated. The serum was administered intravenously. In six of these children, at the time of the intravenous injection, additional serum was given intramuscularly. Fourteen of these children were 3 years of age or under.

Nine other children were given an intravenous injection of an equal volume of normal adult serum during the preeruptive stage.

Aided by grants from the New York, Friedsam and Nathan Hofheimer foundations.

The authors had the cooperation of Dr. William Thalheimer, director of the Manhattan Convalescent Serum Laboratory.

From the Willard Parker Hospital for Contagious Diseases, the Department of Hospitals and the Manhattan Convalescent Serum Laboratory.

1. Thomson, David, and Thomson, Robert: The Role of the Streptococci in Measles, *Ann. Pickett-Thomson Research Lab.* 7: 193 (July) 1931 (comprehensive bibliography).

2. Rivers, T. M.: Recent Advances in the Study of Viruses and Viral Diseases, *J. A. M. A.* 107: 296 (July 18) 1936.

Four other children were given concentrated normal serum<sup>3</sup> intravenously, also during the preeruptive stage. The convalescent serum used by us was processed according to the regulations of the U. S. Public Health Service. The serum obtained from thirty individual bleedings was pooled, so that the age of the serum averaged not more than sixty days after the onset of the measles in the donors.

Normal adult serum was prepared in exactly the same way, the source, however, being healthy normal adults none of whom had recently been ill. Most of these adults had had measles during childhood.

The concentrated serum used was prepared according to the method described by Thalhimer.<sup>3</sup> It was concentrated to one third of its original volume. It was prepared separately for the four different blood types.

RESULTS

Modified measles has a much milder course than the usual measles. The patient is not very ill; the fever is at a lower level and its duration is short. The catarrhal stage is less severe. The eruption is modified

Summary of Results Obtained with the Use of Measles Convalescent Serum

Number of Patients	Amounts in Cc. (at Least)		Clinical Course

in that the maculopapular lesions are discrete, scattered and confined mostly to the face. The cough is not as severe and is of short duration. The posteruptive illness is of short duration, and complications are unusual. Recognition of the modification of the clinical

Chart 1.—The temperature curve in case 17. Measles serum was given intravenously and intramuscularly during the preeruptive stage. A faint rash was noted four days after injection. The temperature was never over 102 F.

course of measles can be made with a fair degree of accuracy.

Measles can be modified in young children if about 5 cc. of convalescent serum is injected intramuscularly from five to eight days after exposure. Once active clinical symptoms are present, larger doses of the serum

would be necessary to modify the disease. We decided to administer the serum intravenously in order to obtain immediate widespread distribution and in the hope that the serum would act more efficiently.

Intravenous injection of pooled human serum, particularly in scarlet fever, sepsis and hypoproteinemia, is a standardized procedure. This extensive experience

Chart 2.—The temperature curve in case 19. Fifty cc. of measles convalescent serum was given intravenously during the preeruptive stage. A faint rash appeared the next day. There was a definite modification of the measles, and the fever continued for two days after the appearance of the rash.

has proved that only rarely does any untoward reaction occur. We felt sure, therefore, that no risk was being taken in the intravenous administration of large quantities of pooled human serum. Empirically we decided to give 50 cc. to the first few patients admitted. From the data thus obtained we could estimate dosage on subsequent patients.

As noted, twenty-four children were injected with measles convalescent serum. Of these, ten patients received the serum two or more days before the appearance of any rash, and the remaining fourteen one day before.

The course of the measles was definitely modified in ten of the twelve children who received 50 cc. or more intravenously. It was definitely modified in five of the six children who were given from 40 to 45 cc. intravenously. Four children received 30 cc. intravenously. There was modification in only the two of the four who were given an additional 20 cc. intramuscularly. There was modification in one child who received 25 cc. intravenously but none in the child who received 20 cc. intravenously and an additional 20 cc. intramuscularly. The intramuscular injections were given at the time of the intravenous injections. The results are given in the accompanying table.

There was a total of five failures and one questionable modification in the twenty-four children treated. From the data obtained it would appear that in order to obtain modification about 40 or 50 cc. of the measles convalescent serum should be injected intravenously at least one day before the appearance of the eruption (charts 1 and 2).

The course of the measles was modified, in that these children were not very ill. The rash was not profuse and was confined largely to the face and upper part of the chest. On the face the rash was morbilliform and was discrete elsewhere. The cough was not distressing and ceased in a few days. In most of the cases fever persisted for about two days after injection (as compared with an expected duration of three or four days). The maximum height of the temperature was perhaps a little less than is to be expected in unmodified measles. If pneumonia was not already present on admission, none of the patients receiving

3. Thalhimer, William: A Simple Inexpensive Method for Concentrating Serum Under Sterile Conditions, Proc. Soc. Exper. Biol. & Med. 37: 258 (Jan.) 1938.

measles convalescent serum gave subsequent evidence of pulmonary involvement.

As mentioned, twelve children received intravenous injections of 50 cc. or more of convalescent serum. In order to ascertain whether the course of the disease could be further influenced, four of these patients were given a second injection a day after the first and one patient was given two additional injections on successive days. This treatment seemed to have some additional effect. The rash did not appear until the injection of the serum was stopped, and it was sparse and modified. We had the impression that the appearance of the rash was being retarded by these successive injections (chart 3).

Four of the twenty-four children receiving convalescent measles serum were severely ill at the time of the discovery of measles. One had peritonitis, the second widespread pneumonia, the third severe rheumatic fever and the fourth severe croup. We feel that their recovery was favorably influenced by modification of the measles.

#### REPORT OF CASES

CASE 6.—V. D., a boy aged 5 years, was admitted April 11, 1937, with a severe nondiphtheritic croup; Koplik spots were noted. He was examined with a laryngoscope; no membrane was present but intubation was necessary. The day after admission 50 cc. of measles convalescent serum was given intravenously. The next day he was much improved and a faint measles rash appeared on the face and the chest. On the same day the tube was removed. A pneumonic infiltration was now present in the right lower lobe. His condition was satisfactory for four days, when the croup returned and intubation was again done. The tube was removed the next day; he improved within a few days and recovered rapidly.

CASE 22.—E. F., a girl aged 13 months, admitted April 28, 1938, had been discharged from Willard Parker Hospital six weeks before. She had been ill with whooping cough and pneumonia. She continued to cough at home. Eight days before the present admission, the child was ill with varicella. Six days later she became very ill, with a severe paroxysmal cough and extreme difficulty in breathing. On admission the child was severely ill; she was cyanotic and the respirations were shallow and rapid. Koplik spots were present. She was put in an oxygen tent. Physical examination and roentgenograms of the chest showed a diffuse pneumonic infiltration. Soon after admission 50 cc. of measles convalescent serum was

Chart 3.—The temperature curve in case 2. Measles convalescent serum was injected intravenously on three successive days during the preeruptive stage. No rash appeared until twenty-four hours after the last injection. The measles was definitely modified.

given intravenously. Another 50 cc. was given the next day. The child's condition improved, and two days after admission a faint rash appeared. The temperature dropped to a normal level. It was found necessary, however, to keep the child in an oxygen tent for a full week. Fine rales heard at the bases of both lower lobes persisted for an additional ten days after removal from the tent (chart 4).

CASE 23.—T. R., a boy aged 4½ years, was admitted May 2, 1938. Four days before admission he had been admitted to

another hospital for an acute attack of appendicitis. At operation a gangrenous appendix with diffuse peritonitis was found. Koplik spots were seen on the third postoperative day and the child was transferred. On admission he was very ill and was given 50 cc. of measles convalescent serum intravenously. The measles was definitely modified, and his temperature returned to normal within three days.

Chart 4.—The temperature curve in case 22. The child was admitted with a severe, widespread pneumonia. Convalescent serum was injected intravenously on two successive days. The measles was definitely modified, the temperature dropped to a lower level and the child improved clinically.

CASE 14.—L. H., a boy aged 9 years, had rheumatic fever with a severe cardiac insufficiency and was admitted to Willard Parker Hospital April 23, 1937, because Koplik spots were found. On admission the boy was very dyspneic, and coarse rales were heard throughout both lungs. He was given 60 cc. of measles convalescent serum intravenously and two days later a faint rash appeared with definite modification of the measles. The child improved and he was returned to the hospital of original admission.

It was important to ascertain whether the injection of an equal volume of normal adult serum would have the same effect on preeruptive measles as the injection of measles convalescent serum. Since nearly all of the donors of normal serum had had measles during childhood, the normal serum contained a small amount of measles protective substance. Nine children were given 50 cc. of normal adult serum intravenously. In seven of the patients the measles was not modified and in two there was perhaps slight modification. In fact, in two of the children clinical and roentgen evidence of pneumonic infiltration subsequently developed. It is obvious therefore that, once symptoms of measles have appeared, the intravenous administration of 50 cc. of normal serum does not modify the disease.

It is necessary to use about four times as much normal pooled serum to cause the same prophylactic effect as is secured by measles convalescent serum. We wondered whether normal serum given in the same ratio during the preeruptive stage would be effective also in the modification of the measles. Assuming this ratio, it would be necessary to inject from 160 to 200 cc. of normal serum in order to obtain modification. This obviously is a large quantity.

We had available some normal serum concentrated to one third of its original volume by the method described.<sup>3</sup> From 50 to 70 cc. (equivalent to from 150 to 210 cc. of unconcentrated normal serum) was given intravenously during the preeruptive stage. Four children were treated with this concentrated normal serum. In three of these children the serum was injected the day before the appearance of any rash. There was some modification of the disease in only one of these three children. On the other child the rash did not appear until four days after the injection and was scarcely visible.

It is our impression that, once measles has developed, concentrated normal serum is not as efficient as measles convalescent serum, even if given in the ratio discussed. We realize that it is hardly fair to draw conclusions from experience with only four patients.

We hope some time in the future to report on the treatment of severe pneumonia occurring mainly in the late eruptive and posteruptive stage of measles. Ten children with pneumonia and measles were injected intravenously with from one to three large doses of measles convalescent serum or scarlet fever convalescent serum. Thus far the results have been of questionable value.

#### COMMENT

Since in virus diseases specific therapy is of little avail once active infection is present, it seemed surprising to us that this dictum does not apply to measles. The etiologic agent of measles is probably a virus. It was of further interest to note that by giving convalescent serum on successive days we thought it could further influence the clinical progress of the disease. The eruptions did not appear until the serum was stopped.

Zinsser<sup>4</sup> states that the immunologic difference between virus infection and bacterial invasion may be eventually explained by the intracellular position of the former. It would appear that virus multiplication requires the cooperation of the body cell (intracellular) metabolism. The cause of injury in virus diseases appears to depend on the metabolism of the invaded cells. Bacteria, in contrast, can multiply and thrive in the body cells, in intercellular fluids and on artificial mediums. Bacteria are more strictly parasites. This difference between viruses and bacteria may be the reason why immune serum can act more efficiently on bacteria. Filtrable viruses apparently are protected by the invaded cell, making it more difficult for the injected serum to act.

In our experience thus far the indications for this therapy apply to the following groups: weak, debilitated and malnourished infants or children; those who have just recovered from one or more of the infectious diseases of childhood, particularly whooping cough, and children who at the time of the development of measles were suffering from a severe, acute or chronic disease, such as pneumonia, rheumatic fever or peritonitis.

Should measles convalescent serum not be available, a transfusion of 125 cc. of whole blood from a donor recently recovered from measles could be used. It should be simple in any community to secure a donor of this kind.

We have not given measles convalescent serum at the height of the eruption. However, we have received from many physicians reports of good results when such serum was given to very sick persons at the height of the eruption. Guibert and Lapeyre<sup>5</sup> and Armstrong<sup>6</sup> also report excellent results when the serum was given at the height of the eruption. We cannot yet evaluate the efficiency of this procedure since clinically it is known that very sick patients improve rapidly when once the rash has reached its maximum.

#### SUMMARY AND CONCLUSIONS

1. The intravenous injection of adequate amounts of convalescent measles serum, if given in the preeruptive stage of measles, modifies the course of the measles in most cases. Twenty-four children were so injected. In nineteen of these children definite modification was obtained.
2. The effective dose is from 40 to 50 cc. given at least one day before the appearance of the eruption.
3. The injection of convalescent serum on successive days seemed to have an additional effect.
4. Normal adult serum given in equal volumes to that of measles convalescent serum caused no modification.
5. The administration of from 150 to 210 cc. of normal serum concentrated to one-third its volume was effective in only one or possibly two of four patients.
6. There is no risk in the intravenous injection of large quantities of properly prepared pooled human serum.
7. This therapy is indicated especially under the following conditions: in weak and debilitated children, in those just recovered from whooping cough and other infectious diseases of childhood, and in those in whom measles developed during the course of another acute or chronic disease. Such children may thus be spared a severe attack of measles and perhaps avoid a fatal or a prolonged illness.

#### PLASTIC SURGERY IN CHILDREN

##### THE MEDICAL AND PSYCHOLOGIC ASPECTS OF DEFORMITY

CLAIRE L. STRAITH, M.D.

AND

E. HOYT DE KLEINE, M.D.

DETROIT

The past two decades have brought forth intensive campaigns in behalf of crippled and otherwise physically handicapped children of this country. Equally serious, but less widely publicized, are the childhood handicaps that are the results of deformity. By "deformity" we refer to those visible abnormalities which handicap their victims because of a peculiar appearance.

As examples of this group, we might cite harelip and cleft palate, facial birthmarks, saddle nose, hunchback, webbed fingers, crossed eyes, ptosis of the eyelid, disfiguring scars, lop ears, crooked teeth and contractures resulting from burns. Many of these are congenital deformities and others are acquired during childhood. Of the acquired group, many might have been prevented or minimized at their onset. In addition to efforts at prevention, the greatest service to such children is the work being done in the correction of such defects by plastic surgery. Plastic surgeons must, of course, give due credit to the achievements of orthopedists, dentists, ophthalmologists and dermatologists, whose efforts have made many other deformities amenable to treatment.

Although the effects of deformity are largely psychologic, the ultimate responsibility for their management generally falls on the shoulders of some physician. It is for these physicians that we present this summary of the pertinent facts relating to childhood deformities. Let it be said at the outset that we are not professional psychologists. We are primarily surgeons interested in

5. Guibert, L. E. M., and Lapeyre, A.: Essai de traitement des formes graves de la rougeole par le sérum de convalescents, *Rev. serv. de san. mil.* 106:823 (June) 1937.

6. Armstrong, J. W.: Personal communication to the author.

the correction of these deformities and our discussion on psychology is derived from personal experience in the management of such cases.

#### PSYCHOLOGIC EFFECTS OF DEFORMITY

1. *Inferiority and Shame.*—The first and foremost mental effect of deformity seems to be that of inferiority and shame. Children are notoriously observant of the unusual. A great deal of undue attention is invariably directed at any cosmetic abnormality possessed by a

Fig. 1.—A, unrepai red single harelip in a girl in her teens. She became excessively self conscious of her deformity at about 10 years of age and quit high school during her freshman year, owing to embarrassment. Subsequently she stayed at home most of the time. B, same patient after repair of the lip. There was also a small groove on the right side which was not altered. "Now," she says, "you can't keep me out of things. I can enjoy life like others."

playmate. There is no attempt on the part of a child to conceal his curiosity or to refrain from remarking about the defect publicly or from ridiculing the afflicted companion. Whether his intentions are malicious or sympathetic, he will be openly frank in his discussions and opinions. In a less purposeful manner he will shun the deformed associate or will force him into an inferior social position. A note of permanence is often added to these childhood stigmas by "dubbing" the deformed child with a derogatory nickname which refers to his defect.

It is little wonder, then, that the great majority of deformed children quickly develop a feeling of inferiority and a sense of shame. Probably this mental factor develops much earlier than is generally realized.<sup>1</sup> We recall two infants about 2 years of age with harelip. One would manipulate his lip while looking into a mirror and the other would hide his mouth with a pillow when any one approached. This "inferiority complex" does not usually become a serious problem until the child enters school. He is then brought to realize his difference from the others and finds that he is not able to acquire the intimate companionships enjoyed by his playmates. As the child matures he becomes increasingly more sensitive. When adolescence is reached a sense of despair and a pessimistic philosophy of life admixed with all sorts of peculiar personality traits have been established.

2. *Modifications of Self Expression.*—Lowrey<sup>2</sup> tells us that personality depends on two fundamental drives. The one is for self expression and the other for conformance with accepted social standards. When these two factors coincide, a pleasing personality develops.

When this is applied to the deformed child, the result is obvious. The deformed child may have every mental and physical faculty for self expression possessed by other children but, because of his deformity, he is either restrained by others or avoids the personal contacts necessary for such expression. Activities are either shunned or altered.

Three reactions may result: First, the child may succumb to these obstacles and accept non-expression as his lot. Second, the child may develop a compensatory overabundance of self expression to satisfy his injured ego. Third, under fortunate circumstances the deformed child may replace the suppressed modes of self expression with alternative ones of equal merit.

3. *Antisocial Tendencies.*—A second important factor in the development of personality is the acquisition of popularity. Before a handicapped child can gain recognition of the group he must first overcome the tendency of other children to maintain the natural impression of abnormality and undesirability. Many unfortunates are inclined to give in to these difficulties and to make no effort to become one of the group. Others become resentful toward their obstacles and mistreatment. Blame for their failures is either inwardly or openly placed on all manner of circumstances and people. From the sociologic point of view, this is the dangerous group. These are the children who may develop distinctly objectionable social behavior, since they often cannot obtain desirable employment, may not succeed in matrimonial ventures and will not maintain friendships. As a result, they may resort to criminal activities. Evans<sup>3</sup> has given an excellent fictitious description of a boy who was taunted and ridiculed with the nickname "Barracuda" because of his ugly protruding teeth. This boy's retaliation was to make good his nickname, becoming a relentless criminal. The author suggests "Thus do the cruelties of youth create rogues."

The rarely spontaneous reaction occurs when the handicapped child sets out to make himself popular

Fig. 2.—A, cleft palate in the same girl shown in figure 1. B, appearance of palate after correction. Palates should be repaired when the patient is 2 years of age to prevent serious speech impediments, which cause untold embarrassment. They can, however, be operated on at any age with great improvement of speech tone, as in this case.

regardless of obstacles. This is a goal toward which mental therapy should be aimed when dealing with handicapped children.

#### SURGICAL CARE OF DEFORMITIES

1. *Prevention.*—Very little is known about the prevention of congenital deformities. Acquired deformities, on the other hand, are largely preventable through

1. Straith, C. L.: Plastic Surgery: Its Psychological Aspects, J. Michigan M. Soc. 31: 13-18 (Jan.) 1932.

2. Lowrey, L. G.: The Effects of Physical Handicaps on Personality, Hosp. Soc. Serv. 13: 237-241 (March) 1926.

3. Evans, E. R. G., R.: Ghosts of the Scarlet Fleet, New York, Farrar and Rinehart, 1931.

safety measures. However, once an injury capable of producing a deformity has been inflicted, the preventive measures employed are entirely dependent on the resources of the physician responsible for its care.

Accidental injuries to the face lead the list of acquired deformities.<sup>4</sup> The management of every injury to the soft tissue of the face requires painstaking care and often demands a slow meticulous repair. Prolonged general anesthesia is often needed to insure the operator's

affected with one or two layers of minute subcuticular sutures<sup>5</sup> (fig. 6). Coarse sutures and skin clips cannot be too heartily condemned, since the resulting irregularities and stitch marks constitute deformities in themselves. If interrupted sutures must be resorted to (as around sharply curved lacerations) they should be of fine horsehair in which only the first double twist of a surgeon's knot has been tied—never completed to form a square knot. This permits accurate approximation but allows some expansion to compensate for edema. Surgical incisions on the face should be similarly treated and, in addition, should be planned to follow Langer's lines of skin elasticity. Bony injuries of the face are specialized problems, the discussion of which is too extensive for this paper. Those who are not familiar with their management are referred to more detailed publications.<sup>6</sup> Let it suffice to mention the difficulties in

Fig. 3.—A, wide single harelip in a newborn infant. Note the flatness of the right ala with distortion of the nasal tip and the wide cleft of the alveolar ridge, through which the tongue can be seen. B, appearance after repair. Harelips should be corrected during the first few days of life under local anesthesia. A few drops of procaine hydrochloride in each infra-orbital foramen and at the base of the nasal septum will suffice. The shock to the child is negligible and the relief to the parents immeasurable.

unhindered freedom to do careful work. The simplest brush burns should be carefully scrubbed with soap and a soft brush to reduce the danger of tattoo marks of oil or dirt (fig. 5). Embedded cinders or grains of dirt must be plucked out one by one. In deeper wounds, all nonviable tissue should be carefully debrided. Small fragments of bone or cartilage, on the other hand, should seldom be removed. These apparently useless bits rarely sequester and are most necessary to maintain the normal contours of the face. Beveled or ragged

Fig. 5.—Bluish oil and cinder tattoo marks resulting from dirty abrasions acquired several months previously. Such deformities are very common among children who are victims of accidents in the street. At the time of emergency treatment this type of disfigurement can often be minimized by thorough scrubbing, under anesthesia, with soap and a soft brush. Satisfactory correction at a later date is almost impossible with such extensive tattooing as this case presents.

early diagnosis of bony lesions. The presence of excessive edema and the absence of severe pain usually hide the existing injury. This is especially true of nasal fractures but applies also to those of the frontal bone, malars, maxilla or mandible. Every injury to the face, however innocent in appearance, should be carefully checked by inspection, palpation and x-ray examination for possible fractures.

Preventive aspects of the care of burns have been more widely publicized. The use of tannic acid should be a matter of routine. The earliest possible skin grafting of burns should also be a familiar sequence. One suggestion might be made about the prevention of con-

Fig. 4.—A, double harelip in a newborn infant. Note the absence of a columella, leaving the midportion of the lip attached directly to the nasal tip. This is an almost universal occurrence in double harelip. B, correction made by Federspiel method. This procedure usually gives a "cupid's bow" shape to the vermilion border, as seen in this case. We prefer to reconstruct the columella at a later date, using all available tissue for the lip at the first operation.

wounds should be carefully straightened and undermined. All lacerations should be approximated with numerous buried white silk sutures and further per-

tractures: As soon as the immediate shock of the burn has passed, all burned flexor surfaces should be placed in full hyperextension and kept in this position for a prolonged period. This involves considerable ingenuity with splints and traction but will minimize almost every contracture resulting from a burn (figs. 7 and 8).

**2. Earliest Possible Correction.**—When a deformity of any type or severity is present the most important single item in the avoidance of undesirable personality changes is the most complete surgical restoration possible at the earliest date that is feasible. This is a hard and fast rule with no exceptions of which we are aware.

Although this may seem obvious, there are nevertheless many parents who are not so advised. The reason is twofold. First, the average physician sees such cases seldom and hence is not informed on the technical aspects of therapy. Second, plastic surgery has undergone such great advances since the World War that the information contained even in standard textbooks of surgery is often obsolete and misleading.

It is of particular importance to have deformities corrected, if possible, before the child enters school. This is the age of greatest mental and social reaction to deformity, from which every effort should be made to

not to be overlooked, is the happiness of parents, who by an early operation are spared months of heartache and embarrassment.

We feel that cleft palates should not be operated on before the child is from 18 to 24 months of age (fig. 2). Earlier than this the palatal tissue is too flimsy to permit adequate repair without tearing. Prevention of speech defects is the paramount aim, and, since most children begin to talk at about 2 years of age, this is the age of

Fig. 7.—A, webbing of the fingers and contracture of the little finger from hot water burns. This 4 year old boy was very much concerned about his deformity and would not tolerate any ridicule from his playmates. Because of excellent home training, he developed a great interest in the correction of his deformity and maintained a pleasing personality in spite of his handicap and the necessity for considerable surgery. B, same after correction with Wolfe grafts from the thigh. The procedure used here to separate the fingers is identical with that used for congenital webbing. Massage and exercise will improve the usefulness of this hand still further.

choice for surgery of the cleft palate. Even after a satisfactory anatomic repair, speech training with hours of patient practice is required to insure a satisfactory speaking voice. In certain cases in which there is difficulty due to shortness of the palate, the Dorrance "push-back" operation may be performed to give the palate its needed length.<sup>7</sup>

Plastic surgery involving the legs or abdomen must usually be delayed until the child passes the diaper age

Fig. 6.—A, extensive facial lacerations resulting from automobile accident. Both inner canthal ligaments were divided and the nasal bones were broken away from the nasal process of the frontal bone. B, canthal ligaments were reattached by suturing them together through the nose. Nasal bones were wired to the frontal bone through small drill holes in each. Lacerations were carefully approximated with subcuticular suturing. Note the almost complete absence of visible deformity after healing. We advise more careful attention to all facial wounds and suturing in such a way that stitch marks and scarring are reduced to a minimum. The use of coarse sutures and skin clips cannot be too heartily condemned.

protect the child. Fortunately, there are but few conditions in which at least partial restoration cannot be made during the first five years of life.

**3. Management of Common Deformities.**—Among the congenital deformities there is a group which allows correction immediately after birth. Most conspicuous of these are the harelips (figs. 1, 3 and 4). In the absence of specific contraindications to surgery, harelip should be corrected during the first week of life. With paregoric for premedication, this repair can be safely and efficiently performed with a simple nerve block anesthesia. We have performed such surgery within twenty-four hours after birth, often with the child sleeping through the operation. The advantage of such early intervention is primarily that the earlier the repair the better the return of both the lip and the bony framework to their normal configuration. This is especially true when there is a cleft of the alveolar ridge. With but few exceptions early repair of the lip results in a spontaneous closure of the alveolar cleft. Second, the younger the infant the more satisfactory the local anesthesia with its added safety. A third indication, one

Fig. 8.—A, contracture of the axilla resulting from a burn. This girl also had extensive contractures of the chest and groin, which were relieved by the insertion of large Thiersch grafts. B, same girl after correction with a Z plasty to bring extra skin into the line of contracture. Note that the surgical scars lie across the axilla rather than longitudinally. This prevents recurrence due to shrinkage of the scar tissue.

because of the danger of infection. This includes the use of skin or fascial grafts taken from the lower part of the abdomen and the upper part of the thighs (figs. 7 and 11).

7. Dorrance, G. M.: *The Operative Story of Cleft Palate*, Philadelphia, W. B. Saunders Company, 1933.

Lop ears are very common and very annoying deformities (figs 9 and 10). The use of corrective appliances or adhesive tape never reduces their prominence and should never be advised because of the false hope that it creates. Very marked lop ears should be corrected before school age to avoid the malicious torment

Fig. 9.—A, hideous lop ears in a young girl which caused her to be nicknamed "flop-ears." Her mother states in a letter: "With all her gumption, she never volunteered to do anything that would place her directly before an audience because of her hair being thin and her ears protruding. When she ran, her hair would fly over her face and, instinctively, her hands would fly up to her head and hide the ears." B, same patient after correction. The mother expresses our point of view when she writes: "I cannot speak or write too emphatically on the absolute advantage of operating on children's deformities before they become of school age. The biggest improvement is in R's disposition. She was always on the warpath if any one looked at her in a questionable manner. She is a much better sport and, consequently, has more girl friends. She used to play with boys almost exclusively because it seemed that they didn't notice her ears, or if they did they rarely commented on them like the girls did. She takes more pride in her appearance. The operation has given her a certain sense of equality with the rest of the little girls."

of derogatory nicknames and teasing. Correction of the less marked varieties depends on the attention they excite in playmates and the child's self consciousness of the abnormality.

Nasal deformities do not usually make their appearance until adolescence (figs. 12, 13, and 14). Hump nose, saddle nose and even the traumatic nasal deformities often do not become apparent until this age, when

Fig. 10.—A, lop ears in a boy. Boys are more frequently troubled by this deformity than girls because of the shorter haircuts. Unless corrected before school age, even minor protrusions give rise to great distress and derogatory nicknames such as "jug-handle" or "mule-ears." B, same patient after correction. An elliptic area of skin is removed from the back of the ear and the scalp. The necessary amount of cartilage is then removed so that the ears will remain at about a 45 degree angle from the mastoid. Adhesive strapping will not reduce the degree of protrusion and is a waste of time for both physicians and parents.

ossification of the nasal bones is complete. During this period the nose is continually changing shape. Many plastic surgeons prefer to delay nasal plastic operations until after these changes are complete, but it is our

opinion that marked deformities, or even minor ones that are causing personality changes, should be corrected in the early teens. At this age children develop an exaggerated impression of personal appearance. Self consciousness flourishes as at no other time in life. It is therefore our policy, if at all feasible, to correct major nasal deformities at this time, even though it may be necessary in some cases to do a secondary plastic operation after the nose has more fully acquired its mature characteristics. Until recently it has been impossible to correct childhood saddle noses with cartilage grafts because of the immaturity and softness of a child's rib cartilage. It is now possible to use preserved adult cartilage and to replace or add to this cartilage at a later date if necessitated by further development of the nose.<sup>8</sup> A minor secondary operation seems insignificant in comparison to the drastic personality changes that often result from self consciousness engendered by a deformity.

We have already mentioned the procedures which should be employed immediately after injury to prevent traumatic disfigurement. If for any reason a deformity of the soft tissue results, the corrective plastic pro-

Fig. 11.—A, congenital ptosis of both upper lids. Note the characteristic backward tilt of the head, to facilitate horizontal vision, and the tendency to let the lower jaw drop. B, same patient after correction by construction of fascial tendons from the tarsus to the frontalis muscle. The father says: "To us, he does not even appear to be the same child that he was before the affliction was remedied. We feel that we have saved him many hours of suffering from ridicule by his schoolmates had his condition been allowed to remain. Even as young as he is (8 years), A. has told us many times that he is glad we had the operation performed and that he looks like the other boys."

cedures must usually be delayed until about three months after healing is complete. This is to allow for complete disappearance of latent bacterial contamination, which is almost invariably present. Even the slightest or most localized recurrence of infection diminishes the perfection of a plastic repair. Bony injuries, on the other hand, allow an attempt at correction any time up to two or three weeks. During this time the possibility of repositioning the fragments by breaking up fibrous union gives greater hope of a satisfactory result than any subsequent reconstructive operations.

#### DEVELOPMENT OF SOUND MENTAL HEALTH

Surgical correction in early childhood is the most valuable method of preventing undesirable personality traits. Unfortunately, early correction of the deformity in some instances is impossible; in others it is impossible to obtain a perfect cosmetic result. Therapy, therefore,

8. Pierce, George Warren, and O'Connor, Gerald Brown: *Reconstructive Surgery of the Nose*, Ann. Otol., Rhin. & Laryng. 47: 437 (June) 1938.

must often be supplemented by special training to prepare the child for his handicap. This so-called "special" training is really not special in any sense of the word. It is the same training that might be recommended for any normal child, with emphasis on certain aspects which are most important to the deformed child.

1. *Courage to "Face the Facts."*—First, the deformed child must learn to anticipate difficulties and to be self reliant. Every effort should be directed toward not allowing the child to be spoiled. This training must begin as soon as the child is born by not responding with a burst of attention every time the baby cries or frets or bumps his head; as the child grows older, the same principles should continue in application. It is impossible to enumerate the method of handling each and every situation as it arises.

Since the deformed child is probably destined for one or many operations with some degree of pain, he should be thoroughly prepared for this ordeal. He should not be cajoled into the physician's office dishonestly by being told that it will not hurt or that the "boogerman" will get him if he doesn't go, or by being told that he is "going down town to get a soda." He should be given

dren's Center has shown us records of a boy with badly disfiguring facial burn scars who stole money for candy to pass around, probably for the same reason. He had been nicknamed "scarface," many children even being afraid to hold his hand in games at school. They also showed us the history of a boy with maladjustment fol-

Fig. 12.—*A*, marked hump nose with overhanging nasal tip in a young girl. We are told that she did not get along well with other girls since she was always under a delusion that she was being picked on because of her appearance. *B*, same patient after correction by modification of Joseph's technic. This alteration in appearance has done a great deal to stabilize her emotional difficulties and to improve her social conduct. The correction of conspicuous nasal deformities at early high school age will make the lives of such girls much happier.

to understand that he may be hurt and should at all times be told by both the physician and his parents exactly what to expect. We have seen children of very tender years who were so concerned about the correction of their deformities that several operations and months of treatment have failed to excite a tear; and we have seen older children howl profanely with anger at the removal of a stitch—both undoubtedly conditioned by their training.

2. *Interpretation of Values.*—The handicapped child is most likely to be deprived of many things commonly sought after for their supposed value; for example, money, friends, esteem, beauty, amusements and romance. Unless such children realize that regardless of group standards in this respect true value depends entirely on the enjoyment they themselves derive, they are apt to do many useless, foolhardy or even dishonest things to attain their desires, especially for friendship. Lowrey<sup>2</sup> describes a handicapped boy with a long history of petty pilfering for the purpose of having money to attract companionships. The Detroit Chil-

Fig. 13.—*A*, saddle nose resulting from a childhood fracture, giving this boy a pugilistic appearance. Athletic injury in childhood is one of the commonest causes of this deformity. At the teen age, personal appearance means a great deal to these children and complexes often result from the self consciousness produced by such a deformity. *B*, after correction with cartilage grafts. Formerly, correction of this defect was impossible owing to the softness of a child's rib cartilage. Now the deformity can be remedied with preserved adult cartilage, as in this case.

lowing a severe burn with prolonged hospitalization who gave his toys away to other children. Judge Healy states that "buying their way" is a common origin of criminal activities in handicapped children.<sup>9</sup>

Parents of such a child should make every effort to help him readjust his sense of values. Above all, he must learn that true friendship exists only in those who like him in spite of his deformity and irrespective of his possessions or ability to do something to "buy" their favor.

3. *Compensatory Education.*—We have already discussed the importance of speech training for children

Fig. 14.—*A*, saddle nose resulting from a blow with a baseball bat. Note the broad flat appearance of such a defect. *B*, correction with two pieces of rib cartilage, one to support and narrow the bridge and one as a strut to raise and narrow the tip. This girl's high school life has been made infinitely happier because of this reconstruction.

with cleft palate and we have indicated that such education is almost as important as the surgical repair. Physical therapy and gymnastics are important for children with orthopedic deformities, and contractures from burns, after correction, frequently require muscu-

9. Deneek, H. L.: Crippled Personalities, *The Crippled Child* 15: 130-133 (Feb.) 1938.

lar rehabilitation. We are told by ophthalmologists that crossed eyes are greatly improved by exercises to develop the use of extra-ocular muscles.

The important phase of compensatory education for most deformed children is that directed toward feasible modes of self expression and, later in life, toward trades and professions which will not be hindered by the deformity. To be successful, this training must follow the child's own interests and talents and should never be forced or predetermined by parents or teachers. Constructive hobbies and employment which keep the child happily occupied in his spare time are of the greatest value. Special training in art, music, athletics, handicrafts and the like should be made available wherever possible.

Whatever type of compensatory education can be worked out, if the child finds one or more satisfying methods of self expression which keep him happily occupied and which receive recognition from others, that child will probably develop along essentially normal lines, regardless of his deformity.

#### SUMMARY

1. The problem of deformities in children is a very serious one which has failed to attract adequate attention within the medical profession. The importance of deformities lies in the severe mental reactions and alterations of personality which result.

2. Many of the acquired deformities are preventable and all can be minimized by more careful attention to injuries and burns in visible areas of the body, especially the face. The technical information regarding this phase of preventive medicine should be more widely publicized among medical schools and medical organizations.

3. In the presence of deformity, the most important single factor in the avoidance of undesirable personality changes is the most complete surgical restoration possible at the earliest date that is feasible. Wherever possible, childhood deformities should be corrected before the child reaches school age, and a few are best corrected within the first week of life.

4. Many childhood deformities have become amenable to plastic surgery with the development of that specialty which has taken place since the World War. Still other deformities can be corrected by orthopedists, dentists, ophthalmologists or dermatologists.

5. In addition to surgical care, deformed children require more than ordinary "bringing up" at home and at school. They must be prepared to face greater hardships than normal persons and should be given special training to compensate for altered facilities for self expression.

1713 David Whitney Building.

**Every Soldier Was Given a Lemon a Day.**—Since ancient times scurvy has often been a scourge of armies in war time. As is well known, the disease is due to the diet being deficient in vitamin C. The patient feels tired, has pains in the joints, the gums swell and bleed. Later the skin becomes covered with petechiae and hemorrhages occur. The soldier can no longer march and is useless. Scurvy was rampant in the Abyssinian army on the Somaliland front. From reports of foreign doctors in the Ethiopian Red Cross, they had over 30,000 cases. There were no cases in the Italian army. What was the reason? A small precaution: every soldier was given a lemon a day.—Castellani, Sir Aldo: Hygienic Measures and Hospital Organization of the Italian Expeditionary Forces During the Ethiopian War, 1935-1936, *J. Roy. Nav. M. Serv.* 24:304 (Oct.) 1938.

## TUMORS OF THE FOURTH VENTRICLE

WINCHELL McK. CRAIG, M.D.

AND

JAMES W. KERNOHAN, M.D.

ROCHESTER, MINN.

The early diagnosis of tumors of the fourth ventricle makes possible a more complete removal of the tumor, greater relief of symptoms, and a lowered operative mortality. Early diagnosis is difficult because tumors of the fourth ventricle produce symptoms of increased intracranial pressure. Our cases in which operation was performed have been reviewed in an effort to emphasize any factors which may help in recognizing the early symptoms and determining the treatment.

There have been very few reviews of tumors of the fourth ventricle in which large series of cases have been analyzed. In the more recent textbooks of neurology, such as those by Wechsler,<sup>1</sup> Grinker<sup>2</sup> or Stewart,<sup>3</sup> the consensus is that tumors of the fourth ventricle produce general symptoms of increased intracranial pressure by obstructing the circulation of cerebrospinal fluid. It is only in the later stages of the growth of the neoplasm that signs referable to the cerebellum, medulla oblongata

or pons may be elicited. Parker<sup>4</sup> drew attention to the periodicity of symptoms which some tumors of the fourth ventricle produce. He also discussed the frequency with which some tumors of the fourth ventricle produce sudden death.

#### REVIEW OF CASES

Eighty-two cases have been included in this review and only the predominant universal symptoms have been listed. In this survey we found that frontal or occipital headache, nonprojectile vomiting, ataxia, visual disturbances including diplopia and nystagmus, and the usual symptoms of intracranial hypertension were the outstanding clinical characteristics. The most successful surgical results were obtained in the cases in which a diagnosis had been made early and removal of the tumor had been effected before there had been any irreparable injury of the brain.

In our series of eighty-two cases (fig. 1) there were thirty-one medulloblastomas, twenty-one ependymomas,

From the Section on Neurologic Surgery (Dr. Craig) and the Section on Neuropathology (Dr. Kernohan), the Mayo Clinic. Owing to lack of space, this article has been abbreviated for publication in THE JOURNAL. The complete article appears in the authors' reprints.

Read before the Section on Nervous and Mental Diseases at the Eighty-Ninth Annual Session of the American Medical Association, San Francisco, June 16, 1938.

4. Parker, H. L.: Tumors Involving the Fourth Ventricle of the Brain, Thesis, 1923.

four oligodendrogliomas, two gliomas of the granular layer of the cerebellum, one epidermoid cyst, three hemangio-endotheliomas, nineteen astrocytomas and one papilloma of the choroid plexus. There was nothing particularly characteristic about the ages of the patients except perhaps in the cases of hemangio-endothelioma, in which the oldest patient was 45 years of age and the youngest patient 17. The rest of the patients were between 2 and 34 years of age.

In seventy-nine of the eighty-two cases, headache was one of the initial symptoms (fig. 2). In thirty-four cases the headache was in the frontal region and in thirty-nine cases it was in the occipital region. In sixty-seven cases vomiting also was one of the initial symptoms; in nineteen cases it was projectile and in forty-eight cases it was nonprojectile. One of the commonest neurologic manifestations was ataxia; in sixty-four cases the ataxia occurred relatively early in the history of the disease. Visual difficulty was a common symptom; thirty-one patients complained of visual impairment and fifty-five complained of diplopia. Hiccup has been a rather predominant symptom in cases reported in the literature but this symptom occurred in only eight of our eighty-two cases. Thirty-four of our patients had a stiff neck. Nystagmus was present in sixty-one cases and a choked disk was found in seventy-four cases. It was rather interesting to know that previous to operation it was necessary to make ventriculograms in only twenty-four cases. In the rest of the cases the localization was so definite that ventriculograms were not necessary. In sixty-two of the cases only part of the tumor was removed but in twenty cases the entire tumor was removed. As one reviews the histories one is struck with the fact that the entire tumor could have been removed in a larger number of cases if relief had been sought earlier in the course of the disease. In most of the cases in which the entire tumor was removed the history indicated that the tumor had been present only a short time. It is also interesting to note that of the thirty-one medulloblastomas thirty were removed partially and one was removed entirely. Of the twenty-one ependymomas thirteen were removed partially and eight were removed entirely. Of the entire group of astrocytomas only four were removed entirely.

The survival period in the cases of medulloblastoma did not seem to depend on the amount of tumor which was removed or on the amount of high voltage roentgen therapy given but on the type of cells found. For example, in one case of medulloblastoma in which microscopic examination of the tumor revealed a large number of astrocytes the patient, who was 34 years of age, lived five years after subtotal removal of the tumor. She was returning to the clinic to undergo a second operation when she died suddenly. In the majority of cases of medulloblastoma the period of survival is from nine months to three years; in cases of ependymoma, however, the life expectancy is much longer, even in cases in which only part of the tumor is removed. One patient with ependymoma lived for eleven years following subtotal removal, before it was necessary to perform a secondary operation. Of the four patients with oligodendroglioma, three lived for from three to four years following operation. One man with hemangio-endothelioma is alive six years and one woman is alive five years after operation.

In reviewing our series of cases it has been noted that during the earlier years of neurosurgery as much

of the tumor as possible was removed at operation, regardless of the type of glioma, and roentgen therapy was used regardless of the type of tumor, while in later years, when we were able to distinguish the ependymomas and the medulloblastomas, the operative procedure varied. It also is interesting to note that during the past few years, after we had become more proficient in the diagnosis of fresh sections of the different types of tumor of the fourth ventricle, we have been more prone to carry out total removal, especially of the ependymomas and the astrocytomas, whereas in cases of medulloblastoma as much of the tumor as possible is removed but the radiosensitivity of the cells makes a radical resection less imperative.

#### PATHOLOGY

It generally has been thought that tumors of the fourth ventricle are more malignant than are gliomas that are found elsewhere in the central nervous system. This may be, and undoubtedly is, true from the clinical and surgical points of view, but cytologically it is not so.

Papillomas of the choroid plexus are rare neoplasms, but they usually grow slowly and can be removed. However, because of their situation in the course of the cerebrospinal fluid they may be implanted elsewhere in the subarachnoid spaces, as described by Hall and

Fig. 2.—Predominant symptoms in eighty-two cases of tumor of the fourth ventricle.

Fentress.<sup>5</sup> Ependymomas that arise from the wall of the fourth ventricle are more common, and we have observed twenty-one cases (not including cases in which operation was not performed) of this type of glioma. As a rule, these tumors grow slowly and lend themselves to surgical removal. In several previous studies we have subdivided ependymomas into three types. The epithelial type contains canals or cavities that are lined with ependymal cells. These ependymal cells simulate epithelial cells. There is another type of growth in which the ependymal cells assume a papillomatous appearance and grow around a core of connective tissue. The stroma frequently undergoes myxomatous degeneration. We have termed this subdivision the "myxopapillary type." There is a large group of ependymomas in which the cells assume no characteristic arrangement and because of its cellular appearance we have termed it a "cellular type of ependymoma." This term is somewhat misleading because cellularity in a general way indicates malignancy, but this group of ependymomas is not necessarily more malignant than the other subtypes. Less than 5 per cent of ependymomas are highly malignant and tend to recur rapidly; however, these malignant ependymomas respond rather readily to roentgen therapy.

5. Hall, G. W., and Fentress, T. L.: Papilloma Choroideum with Diffuse Central Nervous System Metastases, *J. Neurol. & Psychopath.* 14: 108-115 (Oct.) 1933.

Astrocytomas are rather commonly found arising from the tissues around the fourth ventricle. They do not differ histologically in any respect from astrocytomas found elsewhere in the central nervous system. Cushing<sup>6</sup> studied and described seventy-six astrocytomas that occurred in the neighborhood of the fourth ventricle; no further discussion of this type of tumor is necessary as we cannot add anything to his excellent description.

Hemangio-endotheliomas have been found in all parts of the central nervous system, but they are more

Fig. 3.—Tumor of the fourth ventricle presenting below the vermis and the line of incision of the vermis necessary for adequate exposure.

common in the cerebellum than they are elsewhere. These tumors may be associated with hemangiomas of the retina, telangiectasis of the skin, cysts of the pancreas, liver, kidneys or spleen; this syndrome frequently is referred to as Lindau's disease. A hemangio-endothelioma of the cerebellum is usually a small nodule on the wall of a large cyst in the cerebellum; the cyst is usually the result of an exudate from the vascular tumor. This type of tumor is commonly hereditary and is thus of eugenic importance. Hemangiomas unassociated with the formation of cysts or lesions elsewhere in the body do occur in the cerebellum and fourth ventricle.

It is probably true that medulloblastomas which usually arise in the vermis of the cerebellum of children should be included in the group of highly malignant gliomas. We have studied thirty-one medulloblastomas. These tumors have a tendency to implant themselves on the walls of the other ventricles and to be disseminated widely throughout the subarachnoid space. This fact should be kept in mind when roentgen therapy is undertaken for their relief. Medulloblastomas are supposed to respond better to roentgen therapy than other types of glioma. This is another reason why it is important to distinguish histologically between the various types of gliomas found in and around the fourth ventricle; it is impossible to distinguish the various types either clinically or by gross inspection. The extent of surgical removal and the subsequent treatment and prognosis depend to a large extent on the type of glioma found on microscopic study.

# SURGERY

Operation for the removal of a tumor of the fourth ventricle can be conducted with the patient in the upright or prone position. In most cases the upright position allows for a drier operative field and permits better exposure of the fourth ventricle. If the upright position is used, signs of changes in or instability of the blood pressure rarely develop. We have found that blood transfusion or the intravenous administration of physiologic solution of sodium chloride and dextrose during the operation help to reduce the incidence of instability of the blood pressure. In the upright position the operation can be carried out under either local or general anesthesia. We have found it more advantageous to use ether administered by the intratracheal method or to use a combination of intratracheal anesthesia and local infiltration. The Cushing cross-bow incision has been replaced almost invariably by a simple curved incision which is started below the mastoid process on each side and curved upward to just below the occipital protuberance. Sufficient exposure is thus obtained to remove the bone over both cerebellar lobes, the arch of the foramen magnum and the arch of the first cervical vertebra or atlas. Usually the inferior tonsils of both cerebellar lobes are herniated below the level of the foramen magnum and in a certain number of cases one can observe the lower margin of the tumor below the vermis. In order to obtain adequate exposure of the tumor sometimes it is necessary to divide the vermis (fig. 3). On the other hand, when the vermis and the inferior tonsils of the cerebellum are not herniated it is sometimes possible to remove the entire tumor without incising the vermis. It usually is necessary to aspirate the posterior horn of the lateral ventricle before opening the dura. After the tumor of the fourth ventricle has been removed, air can be injected into the posterior horn of the lateral ventricle; when the air bubbles through into the fourth ventricle it demonstrates that the aqueduct of Sylvius is patent (fig. 4). This is much safer than

Fig. 4.—Test for patency of the aqueduct of Sylvius and fourth ventricle following removal of a tumor.

attempting to pass a catheter into the aqueduct, as the latter procedure may produce trauma. Postoperative drainage is sometimes advantageous and can be accomplished by either leaving a catheter in the posterior horn of the lateral ventricle or by placing a small collapsible Penrose drain in the fourth ventricle. Postoperative drainage performs several functions. Regardless of the care with which the closure is made there frequently is a small amount of residual blood in the wound. A Penrose drain can safely be inserted through a stab wound in the center of the flap; it is allowed to

remain in place for twenty-four hours and allows the drainage of cerebrospinal fluid to wash all the blood from the posterior cistern. This obviates the necessity for the absorption of blood and also minimizes the tendency to the development of adhesions. We have now been using drainage in these cases for several years and we have found that it lessens the tendency of a postoperative increase of temperature, the formation of cysts and delayed absorption of the fluid around the posterior cistern. Since the advent of the electro-surgical unit we have used it with success in the treatment of all types of intracranial tumors. However, we have also found that the use of the electric cautery around the floor of the fourth ventricle is sometimes followed by a severe reaction; therefore, removal of tumors of the fourth ventricle is carried out with suction and grasping forceps, and we have found that with care in controlling the hemorrhage very little electrocoagulation is necessary.

#### ADVANTAGES OF EXAMINATION OF FRESH FROZEN SECTIONS DURING OPERATION

Prior to the appearance of the monograph of Bailey and Cushing,<sup>7</sup> in which gliomas were classified histologically into their various subgroups, pathologists and surgeons were satisfied with the diagnosis of a glioma. All these neoplasms were treated alike but it was noted that they varied remarkably in the rapidity of recurrence after partial or even seemingly complete removal. Today the classification of Bailey and Cushing is generally accepted, especially by neurosurgeons. Most pathologists, given adequate time in which to apply special staining methods and to study various sections, can arrive at a correct classification of a glioma which the neurosurgeon has removed. This is important as it helps the surgeon in discussing the prognosis with the relatives of the patient and enables him to anticipate the help that can be expected from roentgen therapy. However, this does not help him in deciding how much of the neoplasm he should attempt to remove at operation. At the clinic the surgeons in general have been taught to, and now do, expect accurate diagnosis by examination of frozen sections of fresh tissue which have been removed for biopsy and they plan their surgical procedures accordingly. Wilson<sup>8</sup> developed this field of surgical pathology about thirty years ago, and since that time MacCarty, Broders and their co-workers have been using fresh frozen sections stained with polychrome methylene blue. In the field of neurosurgical pathology several workers have developed methods for the rapid diagnosis of gliomas. Eisenhardt<sup>9</sup> has successfully used neutral red as a vital stain for smears of gliomas and has described the various types of cells and their processes which are seen in gliomas. Russell<sup>10</sup> has used toluidine blue to stain smears of gliomas. The tissue is smeared on a microscopic slide and fixed rapidly, and the stain is applied. This method also demonstrated the various types of cells and their processes. We have been using polychrome methylene blue to stain frozen sections of fresh specimens of brain tumors for many years and have found it satisfactory. Aside from the fact that we have become used to this method, it seems

to us that it has the advantage of allowing us to study not only the individual cells but also the architecture of the neoplasm. We also can study the relation of the cells to the walls of blood vessels, changes in the blood vessels, especially proliferation of endothelial cells of the intima, and necrosis, mitotic figures and so on. The stain does not, as a rule, demonstrate all the processes of the cells, but diminishing the light which passes through the section makes it possible to visualize most processes. We keep most of our fresh frozen sections for several days, at least until the permanent sections have been made. This procedure allows us to compare the fresh sections with the fixed sections and is useful in teaching. The fresh sections are mounted in a 5 per cent solution of dextrose, and the edge of the cover glass is painted with "duco," which prevents evaporation of the aqueous solution that is

Fig. 5.—Hemangio-endothelioma exposed by dividing the vermis.

used for mounting. The sections may be preserved much longer if they are placed in a dark cold place.

The object of operation in cases of tumor of the fourth ventricle is to relieve the internal hydrocephalus or the increased intracranial pressure. Although a conservative operation which opens the lower portion of the aqueduct of Sylvius may be followed by temporary relief, if the surgeon is made aware of the malignancy of the tumor during the operation his method of attack and his attempt at radical removal are modified by the cytologic character of the tumor encountered.

#### REPORT OF CASES

CASE 1.—A man aged 49 came to the clinic complaining of headache, dizziness and failing vision. Frontal headaches had begun six months previously and a month later he had been seriously ill with influenza. Following this he had felt tired constantly, had had to force himself to work, and nearly every day he had had a mild frontal headache. The headaches had become extremely severe in the six weeks before his admission and he had had to stop work on account of dizziness. His vision gradually had become blurred and the headaches had become more severe. Examination revealed bilateral choked disks of 1 diopter in the right eye and 3 diopeters in the left eye. Neurologic examination revealed a slight increase of all reflexes on each side and some incoordination and ataxia. Ventriculography revealed bilateral internal hydrocephalus and dilatation of the third ventricle. During a suboccipital craniotomy the bone was found to be very thin and when the dura was incised a large reddish vascular tumor could be seen lying below the vermis, which was divided. A specimen of the tumor was removed for biopsy. Histologic examination of this speci-

10. Russell, Dorothy: Personal communication to the authors.

men, which was made during the operation, disclosed that the tumor was a typical hemangio-endothelioma. The growth was dissected from below upward; it was found to fill the fourth ventricle. Many large vessels entered the tumor from the cerebellum. These were ligated and Cargile membrane was packed about the tumor. It was necessary at this point to close the wound. The second stage of the operation was performed two weeks later, when the tumor was removed (fig. 5). After a rather stormy convalescence the patient returned home and was able to resume his duties as editor. When he was seen one year later his general condition was excellent, and two years later he was out making campaign speeches and working as hard as ever. It is now seven years since his operation and he is perfectly well.

Histologic examination revealed that the tumor contained numerous blood spaces, both large and small. The spaces were lined with endothelial cells; in some of the spaces the endothelial cells were swollen and cytoplasm was vacuolated; staining with sudan III disclosed that the vacuoles were filled with lipoids. In some regions the blood spaces were missing and there was an excess of loose connective tissue. However, there was no dense fibrous tissue or blood pigment. Perdrau's silver stain for connective tissue revealed that the reticulum radiated away from the larger blood spaces like the spokes of a wheel.

Fig. 6.—Ependymoma attached on the left side.

There were no evidences of hemangiomas of the skin or retina or of disease of the pancreas or kidneys, and there was no cyst associated with the tumor in the cerebellum; therefore we are not suggesting that this case is an example of Lindau's disease.

In the following case a tumor of the fourth ventricle was diagnosed early and removed entirely. Examination of fresh tissue during the operation disclosed that the tumor was an ependymoma. The postoperative course, which was thereby shortened, was uneventful.

CASE 2.—A girl aged 18 years was referred to the clinic because of headache, vomiting and pain in the neck. She had been perfectly well until ten months before she came to the clinic, when she had begun to have severe occipital headaches. The headaches had been mostly on the right side, had occurred at any time of the day and had lasted from two to three hours. They gradually had receded until they had occurred every two weeks, at which time they had awakened her in the morning. They had been associated with vomiting which had not been projectile or associated with nausea. Immediately after vomiting the headache had been relieved. Five months previous to her examination she had entered college and her vomiting had been attributed to hyperacidity, which had improved temporarily following the daily administration of alkalis and non-acid forming foods. Two weeks before she was examined at the clinic she had noted a dull pain in the back of the neck; the pain had been associated with the headaches. She had had one attack of hiccups. Examination disclosed a slight tremor of the eyelids and hands and tenderness on percussion of the occipital region of the skull. There was no bruit but the neck was slightly stiff. Examination of the eyes revealed that vision

was 6/10 in both eyes. Examination of the ocular fundi revealed a choked disk of 7 and 8 diopters in the right eye and a choked disk of 6 and 7 diopters in the left eye. Examination of the visual fields revealed enlarged blind spots in both eyes. Roentgenograms of the head revealed intracranial pressure and pressure erosion of the sella turcica. A suboccipital craniotomy revealed a tumor of the fourth ventricle. The tumor, which was granular and reddish, extended below the herniated inferior tonsils to the level of the second vertebra. Examination of frozen section, which was stained with polychrome methylene blue, revealed that the tumor was an ependymoma. This examination was made during the operation. The tumor, which was attached to the floor of the fourth ventricle on the left side, was removed completely (fig. 6). Following the operation the patient had a very satisfactory convalescence; on the eleventh postoperative day the choked disks were markedly diminished and her general condition was excellent.

Histologic examination of the fresh tissue which was removed at operation revealed a typical cellular type of ependymoma. The cells were closely packed together and were remarkably uniform in appearance. The nuclei were larger than those of astrocytomas, and the distribution of the chromatin granules was different. The architecture of the tumor also was characteristic as the cells were distributed uniformly throughout the tumor except around the blood vessels, where there was an acellular homogeneous zone. When the polychrome methylene blue stain was used we were unable to see fibrils around the blood vessels. There were a few mitotic figures which suggested that the neoplasm was actively growing, but it is not on this account that we have used the term "cellular type of ependymoma." These observations were confirmed by examination of sections which were stained with hematoxylin and eosin, with Mallory's stain (phosphotungstic acid hematoxylin), with Cajal's gold chloride and sublimate method, and with Hortega's method (ammoniacal silver carbonate). In addition, we found some regions in which the cytoplasm of the cells seemed to be missing; in these regions the tumor had a honeycomb appearance which usually is associated with oligodendrogliomas. We have noted this tendency in a previous study but only occasionally have we been able to prove that the cells are really oligodendroglial cells. We have preserved the original sections which were stained with polychrome methylene blue by the method we have described elsewhere, namely the simple expedient of sealing the coverglass with a solution of "duco." In the sections of the fresh tissue there were no regions in which the cells had a honeycomb appearance, yet the fresh sections had been cut from the same block of tissue which was fixed in solution of formaldehyde embedded in paraffin and used for the sections which were stained with hematoxylin and eosin. It would thus seem that the honeycomb appearance is the result of fixation and not the normal status of the cells.

Ependymomas of the fourth ventricle grow slowly and sometimes produce localizing signs before they produce any evidence of intracranial hypertension. In the following case, throbbing pain and dizziness which occurred on turning brought the patient to his physician, who suspected a tumor of the brain:

CASE 4.—A man aged 40 came to the clinic because of severe throbbing in the back of his head. Ten months previously, while playing golf, he became dizzy when he stooped over and shortly after this he had begun to vomit after almost every meal. Six months before he came to the clinic he had begun to have a severe thumping pain at the base of the skull; he had felt dizzy on arising and sudden attacks of dizziness and vomiting had occurred when he turned suddenly. The roentgenograms of the head were negative; examination of the eyes revealed that vision, the visual fields and the ocular fundi were normal. Neurologic examination revealed mild nystagmus and slight incoordination on the left side. Ventriculograms revealed internal hydrocephalus. A suboccipital craniotomy disclosed a large granular tumor which projected below the vermis and to the level of the first cervical vertebra. Biopsy, which was performed during the operation, disclosed that the tumor was an ependymoma. It was possible to elevate the

lower portion of the tumor and the entire tumor was removed in small pieces. Three years after the operation the patient was well and working every day.

Histologic examination revealed that the greatest portion of the tumor was of the cellular subtype but that here and there throughout the neoplasm were cavities or spaces that were lined with ependyma. The cells lining these spaces had a low columnar, epithelial appearance. The tumor was essentially a slowly growing one, as there was no evidence of mitotic figures or hyperchromatic nuclei and the cells and the nuclei were remarkably regular in size. In a few places the cytoplasm of the cells seemed to be missing and the tissue had a honeycomb appearance commonly seen in oligodendrogliomas.

The malignancy of a medulloblastoma is not the same in all cases; in some adults the malignancy is low. These tumors also are radiosensitive; therefore, partial removal and irradiation frequently are followed by prolonged relief.

**CASE 5.**—A woman aged 27 came to the clinic complaining of pain in the head in the occipital region and loss of vision. Eight months before she came to the clinic she had noticed pain in her head on bending forward. The pain had become worse and for four months before she came to the clinic she had been having projectile vomiting with the headaches. One month previous to her examination at the clinic she had begun to have intermittent diplopia and blurring of vision, associated with a roaring sensation in the left ear. Acute bilateral choked disks of from 3 to 4 diopters were found and neurologic examination revealed a moderate ataxic gait and slight incoordination. Suboccipital craniotomy was performed; the cerebellar convolutions were normal but the inferior tonsils were herniated through the foramen magnum. Incision of the vermis disclosed a large tumor that filled the fourth ventricle (fig. 8). Microscopic examination of a specimen of the tumor, which was made during the operation, revealed that the lesion was a medulloblastoma. It contained spongioblasts and had the appearance of a very malignant tumor with mitotic figures. Subtotal removal of the tumor was accomplished with the electrosurgical unit, sucker and curet. Air then could be seen bubbling through the aqueduct of Sylvius and into the fourth ventricle. Following the operation the patient was given three courses of high voltage roentgen therapy. She remained perfectly well for one year after the operation. She lived six years after the operation. One course of roentgen therapy was given each year. The patient was perfectly well; she was able to do her own housework and to work in her garden. She died suddenly a few days after the symptoms recurred.

#### IRRADIATION

There is probably no other group of tumors in which postoperative irradiation is as important as it is in the tumors of the cerebellum and fourth ventricle. At times we are dealing with a tumor which is highly radiosensitive, that is, a medulloblastoma, and in which it has been suggested that no operation should be done but that the patient should be subjected to at least three courses of irradiation. In some of the foreign clinics, wherever increased intracranial pressure without localizing signs develops in a child, irradiation is advised without operating. We do not agree with this procedure because in some cases of the more radioresistant types of tumor in which the history reveals that the tumor has been present only a short time it can be removed and a cure accomplished. However, in view of the fact that the majority of tumors which occur in the posterior fossa during childhood are medulloblastomas, irradiation after operation is usually indicated.

Cutler, Sosman and Vaughan<sup>11</sup> reported twenty cases of cerebellar medulloblastoma and reviewed sixty-one cases reported by Cushing in 1929. In all

except one case the diagnosis was confirmed by biopsy or by microscopic examination at necropsy. Medulloblastomas implant themselves in the pathway of the cerebrospinal circulation. These authors recommended irradiation of the entire cerebrospinal axis and the use of high voltage roentgen therapy and the administration of a maximal dose to each portal. Because of the sensitivity of the tumors to roentgen therapy the authors said that roentgen irradiation can be used as a therapeutic method for the differential diagnosis of cerebellar lesions which affect children. They recommended a trial of roentgen therapy before cerebellar exploration is undertaken.

Elsberg and Gotten<sup>12</sup> reviewed a series of twenty-three histologically verified medulloblastomas to determine whether conservative surgical procedures, which were characterized by wide decompression and followed by roentgen therapy, or more radical operation or surgical eradication of the tumor plus roentgen therapy gives the best results from the standpoint of operative mortality and survival. They found that the average period of survival of all patients who recover from one or

Fig. 8.—An unusually well encapsulated medulloblastoma of a low grade of malignancy.

more operations was seventeen and three-tenths months. In the ten cases in which only a conservative operation was done the average period of survival was seventeen and a half months, which is a factor of importance in favor of conservative operation for cerebellar medulloblastomas. They expressed the opinion that the immediate effect of the radical operation is apparently produced by the decompression rather than by the complete removal of the tumor and that the length of survival is a consequence of the roentgen therapy of these radiosensitive growths. They concluded that in the treatment of cerebellar medulloblastoma conservative operation has produced better immediate results than has an attempt at radical extirpation and that from the standpoint of length of survival the former procedure has produced results which are at least as good as those obtained with the radical method.

Elsberg, Davidoff, and Dyke<sup>13</sup> have advised roentgen irradiation of tumors in the operating room while the wound is open. They said that medulloblastomas, which occur frequently in the posterior cranial fossa of children, have a vascular base which practically can

12. Elsberg, C. A., and Gotten, Nicholas: The Results of Conservative Compared with Radical Operations in the Cerebellar Medulloblastomas: An Analysis of Twenty-Five Cases, *Bull. Neurol. Inst. New York* 3: 33-52 (June) 1933.

11. Cutler, E. C.; Sosman, M. C., and Vaughan, W. W.: The Place of Radiation in the Treatment of Cerebellar Medulloblastoma: Report of Twenty Cases, *Am. J. Roentgenol.* 35: 429-453 (April) 1936.

never be removed completely and said that a survival period of more than two years is exceptional. Medulloblastomas are very radiosensitive and the results of some occipital decompression for relief of obstructive hydrocephalus, followed by roentgen therapy without any attempt at radical removal of the growth, are as good as if not better than the removal of a large amount of tumor. In all cases of cerebellar tumors they advocated the direct roentgen therapy while the wound was open.

Sachs, Rubinstein and Arneson<sup>14</sup> expressed the opinion that medulloblastomas are definitely influenced by roentgen therapy. In a series of thirty-five cases of medulloblastoma, fifty-two operations were performed. The mortality on the basis of the number of cases was 28.5 per cent. Of the patients who were operated on but who did not receive roentgen therapy, one lived seven months and all the rest died within a shorter time. In the group of cases in which radical operation and roentgen therapy were used, one patient lived fifty-four months, one is still living at the end of seventeen months and one is still living at the end of fourteen months. The operative notes reveal that in this group of cases a thorough extirpation had been done. Necropsy on the patient who lived twenty-nine months disclosed a small local recurrence in the cerebellum. This had not caused any symptoms. Necropsy also disclosed an extensive tumor meningitis which extended the entire length of the spinal cord. They drew the conclusions that roentgen therapy should be preceded by radical operative removal and that high voltage roentgen therapy prolonged the life of patients who have a medulloblastoma.

#### SUMMARY

Tumors of the fourth ventricle do not produce a typical clinical syndrome. However, increased intracranial pressure, a high degree of choked disk, vomiting without nausea, and intermittent severe headache should always suggest a tumor of the fourth ventricle. The treatment consists of suboccipital craniotomy with removal of as much of the tumor as is compatible with the condition of the patient. Postoperative roentgen therapy should depend on the type of tumor found and the amount removed at operation. The use of frozen sections and staining with polychrome methylene blue have made possible the differential diagnosis of tumors of the fourth ventricle at the operating table. This aids in determining the proper surgical procedure.

#### ABSTRACT OF DISCUSSION

DR. F. R. TEACHENOR, Kansas City, Mo.: From these statistics one is impressed with the fact that the tumors encountered are not an exceedingly encouraging group. The statistics are not exactly comparable on account of the different varieties of their statistical tables, with the exception of the astrocytomas, which one naturally expects to give a better prognosis. The prognosis in the medulloblastomas of the fourth ventricle is not a good one. I will confine my remarks to the practical side of the treatment of tumors of the fourth ventricle as far as irradiation and surgery are concerned. Davidoff and Dyke, Cutler and Sosman, and others are recommending the use of irradiation entirely in the treatment of the medulloblastoma. It seems obvious from the symptoms as outlined by Drs. Craig and Kernohan that there are positive means of preoperative diagnosis of the medulloblastoma over any of the other varieties of posterior fossa tumors. In addition to that, one must consider the cases in the stage in which one receives them. Certainly if the

patient is received in the early stage before pressure signs are present one is entirely justified in utilizing irradiation preoperatively. If the patient improves under irradiation, I think it quite consistent that operation be postponed or probably not performed. Most of the patients that I see come in a late stage of compression and approaching a terminal condition. In these instances I do not believe that one is justified in utilizing the x-rays alone but feel that operation is the method of choice and, if the medulloblastoma is the tumor found by microscopic examination, postoperative irradiation of the entire cerebrospinal axis is the best method of treatment. I agree that with the medulloblastoma in childhood below the age of 15 the prognosis as to life is much shorter than above 15. In my experience, two years or two and one-half years is about the limit in children under 15, while of those above I have one that lived five and one-half years with rather interesting symptoms. The patient was first operated on at another clinic for a cerebellar tumor the character of which I did not know, but I saw her some three and one-half years afterward with signs of a tumor of the spinal cord, the symptoms of which came up rather suddenly. I suspected a medulloblastoma, but on account of the suddenness of the onset of the symptoms I removed a pedunculated tumor from the tip of the conus and extended the active life of the patient for a year and a half. I believe that in most instances, particularly in the later stages of the disease, the operative procedure followed by irradiation is the choice, and even though it does cause additional seeding, if the tumor is removed in sufficient quantities to break the block and reestablish the circulation of the cerebrospinal fluid certainly the life period is extended thereby, and with irradiation it may be prolonged.

DR. F. C. GRANT, Philadelphia: In their discussion of the midline cerebellar tumors, the authors did not stress a clinical symptom which is important. Children with cerebellar tumors almost invariably have enlargement of the head. As the tumor interferes with the cerebrospinal fluid circulation, the lateral and third ventricles increase in size and intracranial pressure is raised. In children with incompletely ossified suture lines the sutures separate and the head enlarges. This separation of the sutures often accounts for the absence of choked disk and delays diagnosis. The symptoms of midline cerebellar tumor are notoriously fugitive and difficult to confirm. Absence of choked disk is enough to convince most pediatricians or neurologists that an intracranial lesion is not the cause for the clinical symptoms. But given a child who has bouts of morning headache and vomiting, is clumsy and falls off his roller skates or bicycle with increasing frequency, and in whom on examination nystagmus is absent and signs of incoordination vague and generalized, one should always examine the head. If it seems large and if a cracked-pot sound can be demonstrated, separation of the sutures has occurred and the suspicion that an intracranial lesion exists should be definitely entertained.

DR. W. McK. CRAIG, Rochester, Minn.: One of the penalties of trying to crowd into fifteen minutes a review like this is that some of the important points are omitted, and it is gratifying to have the presentation rounded out by such generous discussion. In treating any type of tumor of the brain the sociologic aspects must be considered. In contemplating surgical measures, one should not forget that they depend on the condition of the patient and on the stage of development of the symptoms. We would like to operate on these patients in the early stages of development of the tumor and remove all of it, but many factors decide whether the operative procedure should be radical, modified or conservative, and sometimes palliative irradiation is indicated, depending, as Dr. Teachenor mentioned, on the stage of development of the tumor at which the patient is brought in for treatment. The value of decision at the operating table, I think, has been greatly enhanced by biopsy and diagnosis of fresh tissue. Knowledge of the type of tumor helps decide between radical and conservative operations. Surgical limitations were illustrated by the fact that, of the eighty-two cases, in only twenty were the tumors totally removed. Of the cases of medulloblastoma, there were thirty in which subtotal removal, and one in which total removal, were influenced by diagnosis of fresh tissue. In the twenty-one cases of ependymoma, there were thirteen subtotal removals and eight total removals, the condition of the patient limiting the opera-

14. Sachs, Ernest; Rubinstein, J. E., and Arneson, A. N.: Results of Roentgen Treatment of a Series of One Hundred and Nineteen Gliomas, Arch. Neurol. & Psychiat. 35: 597-615 (March) 1936.

tion. In the nineteen cases of astrocytoma, there were fifteen in which removal was subtotal and four in which it was total, and in all three cases of hemangio-endothelioma removal was total. Whenever any uncertainty existed as to whether tumor tissue was left behind, removal was indexed as subtotal. I should like to leave the impression that the operative procedure and the results of the operation depend a great deal on the condition of the patient. Our best results were realized in those cases in which diagnosis was made early, a radical procedure was carried out and there had been no irreparable damage to the brain. Dr. Grant's point is very important. We neglected to comment on the appearance of the patient, especially the size and position of the head. One must consider the appearance and the general condition of the patient in determining the surgical approach to the problem.

## AN ACUTE INFECTION OF THE RESPIRATORY TRACT WITH ATYPICAL PNEUMONIA

A DISEASE ENTITY PROBABLY CAUSED BY  
A FILTRABLE VIRUS

HOBART A. REIMANN, M.D.  
PHILADELPHIA

Infections of the respiratory tract are among the most common afflictions of mankind, and pneumonia, which occasionally accompanies or follows them, is the third most common cause of death in the United States. Any progress made in the knowledge of such infections is therefore urgently needed.

Only recently has the physician been armed with comparatively simple methods for the diagnosis of one of these diseases, epidemic influenza, which is now known to be caused by a filtrable virus. Methods for isolating and identifying the virus of the common cold are still too complicated for the average clinical laboratory in routine diagnosis. The discovery of the causative agent of influenza permits separation of the disease as an entity from the undifferentiated group of infections of the respiratory tract and provides a standard, so to speak, against which other entities may be compared. The discovery also confirmed a long established impression gained on clinical and epidemiologic grounds that influenza is a disease entity caused by a filtrable virus.

From studies already made on the group of acute infections of the respiratory tract other than influenza, it is predictable that it is composed of a number of specific entities probably caused by filtrable viruses which remain to be identified, perhaps by methods similar to those by which the viruses of influenza and the common cold were discovered. Efforts in this direction no doubt will eventually make possible a classification of this important group of infections such as has been made with fruitful results in the case of pneumonias of bacterial origin.

With these points in mind, I studied a group of seven cases of an unusual form of tracheobronchopneumonia and severe constitutional symptoms which occurred in 1938. The clinical symptoms and signs of the infection were so uniform in these cases and yet so different from those of other common diseases that I was led to regard the disease as an etiologic entity caused by an unknown agent. I have learned from my colleagues that similar cases were encountered by them in New York, Boston, Philadelphia and elsewhere in 1938. The condition was usually called influenza.

From the Jefferson Medical College and Hospital.

### REPORT OF CASES

CASE 1.—H. M., a man aged 44, did not feel well March 3 while in New York. The next day he felt chilly and hot alternately and noticed a slightly sore throat. He went to bed for two days and was thought by his physician to have influenza. There was profuse sweating. He returned to work but on March 7 had a recurrence of chilly sensations and perspiration. Cough with a slight amount of yellowish sputum developed. He then came to Philadelphia, and entered the hospital on March 8, about the fifth day of illness, as a patient of Dr. Guy Nelson.

He was a robust, severely ill man. His face was flushed and his pharynx inflamed. There were occasional periods of coughing, but no sputum was raised. The heart and abdomen were normal. A few rales were present in the interscapular regions. The temperature, pulse rate and respiratory rate are shown in figure 1. The leukocytes numbered 8,000. A diagnosis of tracheobronchitis was made.

During the first week of observation the temperature remained continuously high, but in contrast the pulse rate was low. There were a frequent hacking cough with scanty mucopurulent sputum, sweating, slight hoarseness, restlessness, abdominal distention, constipation and drowsiness. The patient complained of headache, photophobia and general aching. The breath sounds were suppressed in the base of the left lung posteriorly, where a few rales were heard. The number of leukocytes rose to 11,800. Typhoid was strongly suspected, but no agglutinins for *Bacillus typhosus* were ever demonstrable, and the bacilli were not found after repeated blood cultures and stool examinations.

About the twelfth day of illness the patient was drowsy, perspired freely and coughed occasionally, and the hoarseness had progressed to aphonia. The abdomen was distended, and

Fig. 1 (case 1).—Clinical course. The pulse rate, respiratory rate and leukocyte count were comparatively low in the first week.

the pulse and respiratory rates were increased (fig. 1). The conjunctivas were injected, the tongue was heavily coated and anorexia was present. Two diarrheal bowel movements occurred. The patient was apprehensive at times, drowsy at others and disoriented, especially at night. With the abdominal distention there was a brief attack of acute pain in the left upper quadrant. The patient was extremely ill, and typhoid was still suspected although no proof was forthcoming. A roentgenogram of the lungs showed a faint increased mottling, especially in the right lung.

For the next few days the temperature declined and the pulse rate rose. Profuse sweating continued. Tachypnea continued, and slight dyspnea and cyanosis developed. Aphonia persisted, and the nasal passages became obstructed by acutely inflamed and swollen mucous membranes. The pharynx was dry and

inflamed. Many rales in the base of the left lung and a few in that of the right were now heard. The breath sounds were harsh, but no other abnormal signs except pleural friction were audible in the left axilla. Another roentgenogram, made on the sixteenth day after the temperature reached normal, showed an increased mottled density in both lungs, but particularly on the right side, suggestive of diffuse pneumonia. Garglings

Fig. 2 (case 2).—Clinical course from the first day of illness.

of material from the nasopharynx were made at this time and dropped into the nares of ferrets by Drs. Stokes and Francis, but no virus was isolated.

Numerous rales in the base of the left lung and fewer in that of the right persisted with diminishing intensity. Tachycardia and tachypnea persisted for three weeks after the temperature became normal. The patient lost 12 Kg. (27 pounds) in weight.

Two weeks later, because of persistent aphonia, laryngoscopic examination was performed by Dr. Calvin Fox. The epiglottis, arytenoid processes, vestibule of the pharynx and tracheal wall were inflamed. The vocal cords were congested and thick. Roentgenograms made on the twenty-seventh and seventy-second days showed that the mottling had disappeared, but a haziness over the base of the left lung suggested pleural thickening.

**Laboratory Data.**—The leukocyte counts are shown in figure 1. The percentage of polymorphonuclears was found to be increased to 80 or 90 at each examination. Three blood cultures were negative, and agglutinins for *Bacillus typhosus*, *Brucella melitensis* and *Pasteurella tularensis* were absent. Numerous examinations of sputum and material obtained by swabbing the throat showed the usual nasopharyngeal flora, with *Streptococcus hemolyticus*, *Streptococcus viridans*, *Streptococcus hemolyticus*, diphtheroids, staphylococci, gram-negative cocci and bacilli and on one occasion pneumococcus type XIX. No tubercle bacilli were found. Febrile albuminuria was present. Blood serum

Fig. 3 (case 2).—Appearance on the seventh day of illness. There is a diffuse mottling throughout both lungs, more marked on the right. The interlobar pleura on the right is thickened.

obtained on the sixteenth, thirty-third and seventieth days after the onset of illness and tested by Dr. Francis did not contain antibodies for epidemic influenza virus.

**Summary.**—This patient became ill with the symptoms of a sore throat, recovered to some extent but became worse again and exemplified the so-called typhoid state with tracheitis and bronchitis. Although rales were present in the lungs early in the course of the disease, symptoms and signs of massive inva-

sion were delayed until after the temperature had declined, about the twelfth day. The signs persisted long after the fever disappeared. These observations and persistent laryngitis, hoarseness, aphonia, sweating, dyspnea, cyanosis and drowsiness were the main features. The illness lasted sixteen days.

**CASE 2.**—M. S., a man aged 39, had a herniorrhaphy performed February 25. Convalescence was uneventful until March 11, when he thought he was getting a cold. There was stuffiness of the nose, and pain developed in the left side of the chest. No abnormal signs were present in the lungs. The patient was allowed out of bed, but his discomfort persisted. March 13 he felt generally uneasy, ached all over and felt "grippy." A drenching sweat occurred that night and another on the following night. Fever was noted first March 14 and increased to 38.3 C. (101 F.) the next day, as shown in figure 2. On the third day of fever, sharp pain developed in the lower anterior part of the right axillary region, which was worse on breathing. It became so severe that opiates were required to control it. A few rales were present in this area. The respiratory rate increased to 32. The pharynx was inflamed but was not painful. The leukocytes numbered 9,000.

During the next few days the number of rales increased and the breath sounds were suppressed in the base of the right lung. Occasional pain occurred in the root of the neck on the right side suggestive of the referred pain of diaphragmatic pleurisy. There was no cough and no sputum. Rales appeared in the base of the left lung. Epistaxis occurred on the sixth day.

Fig. 4 (case 3).—Clinical course.

The abdomen was distended and constipation was present. A roentgenogram of the chest (fig. 3) made on the eighth day showed diffuse increased mottled shadows throughout both lungs, more prominent on the right side, suggestive of diffuse pneumonia (Dr. Karl Kornblum). The interlobar pleura was thickened on the right side, and density at the base suggested a small collection of fluid. At about this time the patient complained of pain and numbness in the right wrist, elbow and shoulder. His legs and teeth ached. There was profuse sweating most of the time. One night his gown was changed fourteen times. Physical signs of fluid appeared in the base of the right lung. Dyspnea and cyanosis appeared and became distressing, but there was no cough or sputum. Nasopharyngeal secretions were obtained about this time by Drs. Kinney and Magill and inoculated intranasally into ferrets, but no virus was recovered. A blood culture was sterile. The temperature began to decline after the eighth day, and the patient improved. Dyspnea, cyanosis and sweating diminished. Atropine sulfate controlled the excessive perspiration. A symmetrical patch of hyperesthesia 3 or 4 inches in diameter was noted on the anterior surface of both thighs. The patient began to cough occasionally on the eleventh day and felt that his nose was plugged up again.

A small fleck of blood-tinged tenacious sputum was raised, which contained *Streptococcus viridans*, *Streptococcus hemolyticus*, *pneumococcus* type XIX, diphtheroids and gram-negative cocci.

Thoracentesis was performed, and 300 cc. of bloody, turbid fluid, which was sterile on culture, was obtained. The process was repeated three days later and again on the twenty-second day. Fluid of similar quality and quantity was removed. On the nineteenth day a roentgenogram showed a diminution of the density of the infiltration seen previously. There was an irregular density at the base of the right lung, and there were a few patches of density in the base of the left lung. Low grade fever persisted. Several weeks later a trocar and drain were inserted by Dr. Nassau. The fever increased, and on the fifty-third day the patient suddenly died. Necropsy was not performed.

This patient was observed from the first day of illness; this began as an ordinary infection of the respiratory tract, but profuse perspiration and severe pleuritic pain developed. Evidence of pulmonary invasion appeared about the fourth day and rapidly involved both lungs. Sterile pleural effusion was present. The chief features were the diffuse atypical pneumonia, drenching sweats, dyspnea, cyanosis, severe pleuritic pain and a minimal amount of cough and sputum.

Nasopharyngeal washings were obtained on the eighth day of illness, too late, perhaps, according to the experiences of British investigators,<sup>1</sup> for a virus to be obtained. The blood serum did not contain antibodies for the virus of epidemic influenza.

Experience with these two patients led me to suspect that I was dealing with an unusual form of infection, so that when the next patients were seen, while the first two were still under observation, attempts were made to obtain a virus earlier in the disease. March 20 and March 22, nasopharyngeal washings were obtained at my request from patients 1, 2, 3 and 7 by Drs. Stokes and Kinney of the University of Pennsylvania and Dr. Francis and Magill of the Rockefeller Institute.<sup>2</sup>

Fig. 5 (case 3).—Appearance on the fifth day of illness. The hilar shadows are increased in density. There is a diffuse mottling in both lungs, with a denser shadow in the middle of the left lung field.

CASE 3.—Mrs. K. A., aged 48, first noticed a "head cold" March 12. Her brother had a similar infection at the same time. The patient, her brother (patient 4), her son (patient 5), a friend (patient 6) and her mother (patient 7), among others, were together at a party March 12. Mrs. K. A. felt unduly warm at the time and had chilly sensations the next day, but disregarded them. During the following days the symptoms of a cold persisted, and March 17 they became worse. March 18, fever and coughing began. Chilly sensations recurred, and pain developed in the left side of the chest. The temperature rose to 40 C. (104 F.). The patient was admitted to the hospital on the third day of severe symptoms (fig. 4).

At examination she was restless, apprehensive and overalert. There were slight cyanosis and a hacking, nonproductive cough. The pharynx was slightly inflamed. Marked hyperesthesia was present over both mammary regions. Rales were heard in both interscapular areas and in the bases of both lungs. There was tenderness in the right upper quadrant of the abdomen. The leukocytes numbered 11,800; 81 per cent were polymorphonuclear cells. A blood culture was sterile. Cultures of naso-

pharyngeal secretions obtained with a throat swab showed *Staphylococcus albus* and pneumococcus type IV among other forms of bacteria. A roentgenogram revealed an increase in the usual density of the hilus and vascular markings in both lungs. The temperature and pulse rate were high (fig. 4).

The next day more rales were heard in the base of the right lung and the breath sounds had a faintly tubular sound. Nasal washings were made by Dr. Kinney on the fourth day of illness and inoculated intranasally into ferrets. A virus was isolated.

On the fifth day the patient was severely ill and was stuporous at times. Many rales, egophony, pectoriloquy, weak bronchophony and tubular breathing were now heard in the base of the left lung. There was slight rhythmic flaring of the alae nasi. X-ray examination revealed a diffuse density in the mid-portion of the left lung

(fig. 5) and an increase in the hilar shadows noted two days before which was suggestive of diffuse bilateral pneumonia. During the next few days the patient became considerably worse. On the sixth day, after being urged to raise sputum, she raised the first sample of bloody, tenacious sputum, which contained *Streptococcus viridans*, *Streptococcus hemolyticus*, gram-negative cocci and a few type IV pneumococci. Throat washings were obtained at this time by Dr. Magill and inoculated into ferrets. A virus was obtained which was apparently similar to the one obtained by Drs. Stokes and Kinney two days before.

The patient became irrational. Her face was flushed, the mucous membranes were cyanotic and the lining of the mouth, which had felt uncomfortable for several days, was spotted with bright red discrete and confluent macules, some of which contained papules and whitish speckles. Coarse rales were heard in both mammary regions. Pleuritic pain and friction sounds were present in the left axilla. Dyspnea was severe and she appeared to be gravely ill. Oxygen therapy relieved the dyspnea and cyanosis considerably. On the eighth day euphoria and overalertness, with slight mental confusion and disorientation, developed. The skin over the mammary region was hyperesthetic; touch-

ing and pinching it caused pain. There was tympany in the left mammary region but no rales were heard. Posteriorly there was dullness in the base of the left lung, with decreased tactile fremitus, loud bronchial breathing, egophony and pectoriloquy. A small area where weak bronchial breathing and rales were heard was found in the right base. The leukocytes numbered 15,800.

On the ninth day muscae volitantes and headache were complained of and the patient became more drowsy. She slept most of the time and appeared to be toxic. Various groups of muscles twitched from time to time. The reflexes were generally hyperactive, especially the patellar reflexes. Encephalitis was suspected, but the spinal fluid was normal in all respects and contained two leukocytes per cubic millimeter.

Gradual improvement then began. Herpes appeared on the lip. A roentgenogram on the thirteenth day showed that

Fig. 6 (case 7).—Clinical course from the first day of illness. Note the low pulse rate.

Fig. 7 (case 9).—Appearance on the fourth day. There is a large area of density in the left lung. The left dome of the diaphragm is slightly elevated. The root shadows on the right side are denser than normal.

L.: A Study of Epidemic Influenza with Special Reference to the 1936-1937 Epidemic, Medical Research Council, Special Report Series, No. 228, London, His Majesty's Stationery Office, 1938.

2. Drs. Stokes, Kinney, Francis and Magill performed most of the animal and serologic tests.

the lungs had become relatively clear except for haziness at the base of the left one suggestive of pleural thickening. The number of leukocytes dropped to 9,000.

Improvement was rapid after the sixteenth day, and the patient left the hospital on the twenty-fifth day for further convalescence. She had lost about 7 Kg. (15 pounds) in weight. Rales and friction sounds were still present in the

base of the left lung. She was reexamined on the forty-third day. Her temperature was 37.3 C. (99.2 F.) and she felt weak. A roentgenogram showed thickening of the interlobar pleura between the upper and lower lobes of the left lung but no other abnormalities.

**Summary.**—The illness apparently began as a mild infection of the upper part of the respiratory tract, which was followed after several days by severe tracheobronchitis and diffuse pneumonia. In spite of the

Fig. 8 (case 9).—Appearance on the tenth day. The patch of density in the left lung shown in figure 8 has disappeared, but there is now a diffuse mottling of both lung fields. Plates made on the twenty-third and forty-third days showed progressive diminution of the abnormal densities until the seventieth day, when the lung fields appeared normal.

pulmonary involvement and hacking cough there was practically no sputum. Dyspnea, cyanosis, photophobia, stupor, nervous symptoms and pleuritic pain were conspicuous characteristics. Sweating was not prominent. Rales and roentgenographic evidence of pleural involvement were still present two weeks after the temperature became normal. The type IV pneumococci recovered from the sputum were regarded as commensals without significance.

Nasopharyngeal washings from which an apparent virus was recovered were obtained on the fourth day by Dr. Stokes and on the sixth day by Dr. Francis. Blood serum for tests was

Fig. 9 (case 9).—Clinical course from the second day of illness. Note the low pulse rate and the low leukocyte counts early in the illness. The blood pressure rose during the course.

obtained on the same days, on the forty-third and on the one hundred and twentieth day but contained no antibodies for the virus of epidemic influenza.

Patients 4, 5, 6 and 7, as mentioned, had been in contact with patient 3 when they attended a gathering March 12 at which several members of her family and

a few friends were present. Mrs. A. (patient 3) and her brother did not feel well at the time. Within the next week Mrs. A.'s son, a friend and her mother became ill.

**CASE 4.**—Mr. B. (brother), aged 45, became ill about March 12, feeling cold, shivery and "grippy." He kept on working except for one day in spite of his illness, which lasted about two weeks. There was an annoying dry cough but no sputum. He was examined twice about the ninth day of illness by Dr. Burgess Gordon, who noted rales in both interscapular regions on both occasions. The temperature, taken on two occasions, was normal.

**CASE 5.**—J. A. (son), aged 25, noted dryness of the throat March 14. Two days later the throat was very sore. Rhinitis, malaise and muscle pains were present. It hurt to bend the neck forward. The patient did not go to bed. There was no fever or cough. These symptoms lasted three days and gradually disappeared, so that by the eighth day only soreness of the muscles of the neck was noted.

**CASE 6.**—Dr. C., aged 57, a friend, had rhinitis and sneezing March 16. He felt hot but did not take his temperature. He continued to work but the next day did not feel well. There were epigastric pain, cough with a small amount of sputum, slight diarrhea and pain. When the temperature rose to 38.3 C. (101 F.) he went to bed. There were headache, anorexia, a disinclination to move and muscle pains "as in influenza." The patient recovered after four days.

The symptoms of patients 4, 5 and 6 would generally be regarded as those of a cold and agree with the criteria laid down by Stuart-Harris and his associates<sup>1</sup> for what

they call the febrile catarrhs as differentiated from influenza. It would be highly valuable to know whether a single virus caused this "house" epidemic of disease of the respiratory tract, in which patients 3 and 7 had a severe form, and the others had a mild form. The fact that mice inoculated with nasopharyngeal washings from patient 3 and with blood serum from patient 7 seemed to be made ill by a similar filtrable infectious agent lends support to the hypothesis.

Attempts to solve the problem by immunologic methods are under way.

**CASE 7.**—Mrs. B. (mother), aged 76, noted dryness of the throat and cough about March 16. I saw her March 19, at which time her face was flushed and she appeared to be ill although her temperature was 36.1 C. (97 F.). In the afternoon she became much worse. There was no chill, but the temperature rose to 40.3 C. (104.5 F.) and she was put to bed. She was somnolent and confused, failed to cooperate and was incontinent of feces and urine. She remained at home and was attended by Dr. Burgess Gordon. He found evidence of extensive bronchitis and rales in the base of both lungs. During the next few days high fever persisted, the pulse rate was low and the respiratory rate was 30 per minute, as shown in figure 6. The patient perspired profusely, was cyanotic and coughed but raised no sputum. Pharyngeal exudate was obtained by a swab and inoculated into a mouse. Type IV pneumococci were present. There was constipation, and about the sixth day tympanites, present from the beginning, became severe, tachycardia developed, and the patient appeared to be

Fig. 10 (case 11).—Appearance on the twenty-first day of illness. There are disseminated nodular areas of density in both lung fields. The shadows in the bases, especially in the right, suggest consolidation.

moribund. She was comatose up to the eighth day and confused mentally for a week thereafter. After the eighth day the temperature declined and recovery ensued.

Nasopharyngeal washings were obtained on the fourth and sixth days by Drs. Kinney and Stokes and Magill and Francis, but no virus was obtained. However, blood serum inoculated intracerebrally into white mice by Dr. Francis caused the mice to become ill after twelve or eighteen days. An occasional animal died. The virus apparently died out after the fourth passage.

Patients 8, 9, 10 and 11 were seen in May, June and August and had had no contact with the patients previously described or with any one else with a similar disease. Patient 8 was regarded as having influenza, and in case 9 suspicion of typhoid or psittacosis led to a delay in obtaining nasopharyngeal washings to be examined for a virus until the eighth day.

CASE 8.—Dr. H. C., aged 27, a patient of Dr. George Major of Reading, Pa., had a feeling of malaise, dryness of the throat which developed into a sore throat, hoarseness and cough in the afternoon of May 17. At 9 p. m. a chill occurred, and the temperature then rose to 40 C. (104 F.). The patient had to go to bed, but the next morning there was a remission of symptoms and he resumed his work. He felt fairly well until evening, when fever and malaise returned. For the next few days there were great prostration and weakness and the temperature hovered about 40 C. (104 F.), the pulse rate between 100 and 110, the respiratory rate between 20 and 40 and the leukocyte count between 7,000 and 12,000. The patient was extremely ill, perspired profusely and was greatly distressed by a continuous hacking, unproductive cough. There were photophobia, conjunctival injection and lacrimation. Small amounts of sputum were raised, and numerous cultures of it revealed staphylococci, Friedländer's bacilli and hemolytic streptococci but no type specific pneumococci. A blood culture was sterile.

I saw the patient on the seventeenth day of illness, at which time there was diffuse pneumonia and restlessness, apprehension, headache, sweating, nasal obstruction, cyanosis, severe dyspnea and cough, which were prominent features. Nasopharyngeal washings were made at this time and sent to Dr. Francis, who inoculated them into ferrets but failed to recover any virus. The blood serum contained no antibodies for the influenza virus.

During the second and third weeks of the illness the temperature declined, but the pulse rate rose to 120 and 130, the respiratory rate to 50 and the leukocyte count to 12,000 and 16,000. The temperature rose again to 38.9 C. (102 F.) on the twenty-second day and followed an irregular course, gradually becoming lower; it remained normal after the forty-first day.

CASE 9.—Miss H. A., aged 38, noted discomfort in the abdomen after a dietary indiscretion June 10. There was no diarrhea or constipation, and the discomfort disappeared after a few days. June 18 she had chilly sensations, and pain developed in both eyes. She was very sleepy June 19 and the ocular pain persisted. June 20 she was awakened by cough, chilliness, pain and soreness under the sternum. The temperature varied between 37.8 C. (100 F.) and 39.4 C. (103 F.). Chilliness recurred several times in the next day or two and was accompanied by sweating, which was perhaps caused partly by the taking of acetylsalicylic acid. Cough was frequent, but no sputum was raised. The patient was admitted to the hospital on the third day of illness.

The voice was slightly hoarse, and the mucous membranes of the eyes, nose and pharynx were reddened. The tongue was heavily coated. No abnormal sounds were heard in the lungs. There was slight abdominal distention. A tender lymph node the size of a hazelnut was palpable under the ramus of the mandible on the right side.

Because of the high fever, relatively slow pulse and leukopenia (4,800 cells), the patient was isolated as presumptively having typhoid.

The chief complaints in the first few days were pain in the eyeballs, photophobia, intense frontal headache and cough. There were hoarseness, congestion of the conjunctival and oral mucous membranes and duskiness of the face. Paroxysms of cough occurred frequently but were not productive. The patient was drowsy at times almost to the point of stupor, apart from the occasional narcosis from codeine given for headache.

No abnormal sounds were heard in the chest until the fourth day, when Dr. Tocantins detected harsh breathing and a few rales in the left infraclavicular region and a few rales in the left scapular region. A roentgenogram made at the bedside revealed a patch of increased density in the periphery of the left lung between the second and fourth ribs, and the left side of the diaphragm was somewhat high, as shown in figure 7. By request a small fleck of sputum was raised; it was raised with difficulty and contained a few indifferent streptococci, *Micrococcus catarrhalis* and diphtheroids.

When I examined the patient on the seventh day the only abnormal sign I could detect in the chest was diminished breathing in the left scapular area. The patient now had no complaints except headache, photophobia and cough, but she appeared to be gravely ill. On the eighth day a profuse drenching sweat occurred. Rales returned in the left lung, and the inspiratory breath sounds became harsh and sibilant. Sonorous and rasping sounds were heard. Dyspnea was present and cyanosis appeared. A roentgenogram showed that the localized density in the left lung had almost disappeared, but the whole left lung now seemed faintly clouded. The early density may have been caused by atelectasis. By this time it was obvious that the patient did not have typhoid, and the pharyngeal secretions were collected by Dr. Stokes and inoculated into ferrets. A small amount of white creamy sputum raised with difficulty was inoculated intraperitoneally into mice to determine whether the psittacosis virus was present and into guinea pigs to test it for tubercle bacilli. The leukocyte count remained low. On the seventh and eighth days the patient was given a total of 8 Gm. (120 grains) of sulfanilamide. There was no evidence of any effect.

During the next few days the cough was distressing and stupor was present but the patient was lucid on questioning. She lay on her right side to lessen the cough. Cyanosis deepened, and dyspnea was at times distressing. Vomiting occurred several times, there were periods of drenching perspiration, and headache and photophobia persisted. The spleen and liver were not felt. Abdominal distention and constipation were present.

Many rales, suppressed breath sounds and dulness were present in the lower part of the left lung and tympany above; suppressed breath sounds and wheezing were heard in the right side. A roentgenogram made on the tenth day showed a diffused mottling composed of nodular densities in both lung fields (fig. 8).

No unusual events occurred in the following few days except an occasional drenching sweat. Dyspnea and cyanosis persisted and were worse after coughing attacks. No sputum was raised. Oxygen greatly relieved the dyspnea. The temperature, pulse rate, respiratory rate, number of leukocytes and blood pressure during the illness are shown in figure 9. The pulse rate, low in the beginning, rose. The respiratory rate was never rapid. The blood pressure decreased temporarily and then increased. On the seventeenth day friction was palpable and audible in the lower anterior part of the right axillary area, where the patient complained of pain. Evidence of pleuritis disappeared after a few days. Flaring of the alae nasi was noted. In an attempt to get another sample of sputum Dr. Clerf made a laryngoscopic examination. The mucous membranes were found to be markedly congested and covered in places with a thick, white, tenacious exudate. Some of the exudate was obtained, cultured and inoculated into mice. The animals recovered. The leukocyte count rose to 17,000.

The patient improved gradually and the symptoms slowly disappeared, but tachycardia persisted and the tongue was heavily coated. A roentgenogram showed gradual clearing of the density in the lungs. Numerous rales and wheezes persisted. On the twenty-third day another profuse sweat

occurred. By the thirtieth day improvement was evident. Many coarse rales were still present in the base of the left lung, but the base of the right lung was almost clear. Tachycardia was present. Bronchoscopic examination by Dr. Clerf revealed inflammation of the whole tracheobronchial tree; it was especially prominent in the lower branch of the left bronchus, which contained thick white exudate. The exudate was again injected into mice. There was a weight loss of 11 Kg. (24 pounds).

When the patient was discharged, forty-three days after the onset of illness, the temperature was normal but the pulse rate hovered between 90 and 110. There were many coarse rales in the lower lobe of the left lung. A roentgenogram showed intensification of the bronchovascular markings, although this was less than before. Density was present in the bases of the lungs, especially in the base of the right lung.

**Laboratory Data.**—Slight secondary anemia was present. Many stippled erythrocytes were present in the early period. Each examination showed a persistent increase in the proportion of polymorphonuclear cells, the percentage being between 80 and 90. Döhle's bodies were present in the neutrophils. Febrile albuminuria was present. Four blood cultures were sterile. No typhoid bacilli were present in the stool. Agglutinins for *B. typhosus*, *Brucella abortus* and *Pasteurella tularensis* were absent. The sputum was examined and cultured seven times. The usual flora of the nasopharynx were present, streptococci predominating. No tubercle bacilli were found by culture or inoculation of guinea pigs. Psittacosis did not develop in any of the mice inoculated with sputum. The blood serum contained no antibodies against the influenza virus.

**Summary.**—Typhoid with bronchitis was strongly suspected until evidence of pneumonia developed on the fourth day. Psittacosis, tularemic pneumonia and military tuberculosis were then suspected until ruled out. A roentgenogram revealed a shadow in the left lung which disappeared a few days later, to be replaced by diffuse shadows in both lungs. Dyspnea, cyanosis, drowsiness, hoarseness, dry cough, abdominal distention, headache, photophobia and pleurisy were prominent symptoms and signs. Visual evidence of laryngitis, tracheitis and bronchitis was obtained. There was a hacking cough, and practically no sputum was raised. Pharyngeal washings were obtained on the eighth day of the disease, but no virus was recovered.

**CASE 10.**—Mrs. T. P., aged 35, a patient of Dr. M. J. Sokoloff, felt tired July 11 and had a shaking chill the next day. Because of fever and malaise she was kept in bed for three days. She improved but on July 15 became worse. There were slight sore throat, conjunctival injection, headache and photophobia. Cough began July 19. It was paroxysmal, dry and racking. Profuse sweats occurred, especially at night. The patient was admitted to the hospital July 21, the tenth day of illness. The temperature was 39.5 C. (103 F.), the pulse rate varied from 100 to 120 and the respiratory rate was about 30 per minute. The tonsils and pharynx were inflamed. There were frequent paroxysms of cough and dyspnea, but no sputum was raised. Cyanosis was present. Signs of atypical pneumonia were present in both lungs. A roentgenogram showed diffuse mottling in both lungs, most dense at the bases. The leukocytes numbered 9,000. Cultures of material obtained from the pharynx showed a mixture of bacteria, chiefly *Streptococcus viridans*, *Micrococcus catarrhalis* and gram-negative bacilli. There were no pneumococci. A blood culture was sterile.

The temperature was irregular and gradually declined until the twenty-second day. Cough, cyanosis and sweating persisted, and the patient was gravely ill. Subsequent leukocyte counts varied between 6,000 and 10,000. The temperature rose again on the twenty-third day and followed an irregular course, averaging 37.8 C. (100.4 F.). Dyspnea, cough, sweating and headache were distressing. On the forty-second day the patient became irrational and complained of severe headache, pain and stiffness of the neck. There was occasional vomiting. I saw her at this time. There were photophobia, inflammation of the pharynx and signs of bilateral pneumonia. The reflexes were variable; Kernig's sign, Babinski's sign and ankle clonus could

be elicited at times. Encephalitis was suspected, and the spinal fluid was examined. It was under 220 mm. of water pressure and contained 270 cells per cubic millimeter and 74 mg. of protein per hundred cubic centimeters. A portion of it was sent refrigerated to Dr. Francis for inoculation tests. The patient was somewhat relieved after the removal of 10 cc. of spinal fluid, and two days later 10 cc. more was removed. This contained 350 cells per cubic millimeter, 78 per cent of which were polymorphonuclear cells. Neither sample contained bacteria. A portion of the second sample was injected intracerebrally into eight mice and into the footpads of three guinea pigs. No virus was isolated. The spinal fluid when examined again a week later contained 290 cells, 91 per cent of which were polymorphonuclears. The patient's condition was grave, and her state varied between coma and lucidity. The reflexes were variable, the pupils reacted sluggishly to light and slight rigidity of the neck persisted. The temperature rose to 40 C. (104 F.), the pulse rate diminished to 70 or 80 and the respiratory rate was 30 per minute. The patient was incontinent of urine and feces. During the next few days she became worse; strabismus, pupillary dilatation and insomnia were present. The ocular fundi were normal. Death occurred on the fifty-fifth day. Permission for postmortem examination was not obtained, but a roentgenogram showed a diffuse haziness and fine mottling of both lungs.

The clinical record of the pulmonary infection in this case closely resembles that in the other cases reported, but, as in one of Scadding's cases, death occurred from meningo-encephalitis. Thus the same problem is raised as pertains to the relation of influenza and the encephalitis which occasionally follows it; namely, are the pulmonary and nervous symptoms caused by one agent or by different agents? No virus was recovered from the nasopharyngeal washings or from the spinal fluid.

The following case was studied at the University of Minnesota hospital in 1934, but the report is included here because of its similarity to the cases of 1938:

**CASE 11.**—A man aged 36 was chilled Oct. 29, 1934. Next day he noted chilly sensations, fever and sweating. On the third day he had a severe chill, sore throat and profuse perspiration, and he went to bed for a day or two. He then returned to work but soon felt chilly and again sought his bed, with a relapse of high fever and generalized aching. He tried to get up but could not because of dyspnea on exertion and severe sharp pain in the left side of the chest. He entered the hospital on the ninth day complaining of difficulty in breathing, sore throat, fever and severe pleuritic pain in the right side. He was slightly cyanotic and had labored breathing and a reddened pharynx. There was slight dulness and a few rales in the lower lobe of the left lung, dulness and bronchial breathing in the base of the right lung and friction sounds in the right axilla. Leukocyte counts varied from 4,000 to 8,000. As the disease progressed there were recurrent attacks of drenching sweats, but there was little or no cough. A few specimens of sputum and material obtained with a swab usually contained bacteria which were predominantly staphylococci. Material aspirated with a needle from the consolidated area of the lung was sterile. The temperature was high, 39.5 C. (103 F.) until the eleventh day, after which it averaged about 38.3 C. (101 F.). It became normal on the twenty-seventh day. The pulse rate varied between 85 and 120 but usually was about 100 per minute. The respiratory rate reached 30 per minute on the twelfth day but was about 22 thereafter in spite of the dyspnea and cyanosis. Blood cultures were sterile. Other serologic tests for typhoid fever, undulant fever and tularemia were negative. A roentgenogram of the patient's chest is shown in figure 10. The tuberculin test was negative during the illness and after recovery. Early in the course of the illness influenza, atypical pneumonia, pulmonary mycotic disease and military tuberculosis were suspected. Later in the course, one physician suggested typhoid with bronchitis. The roentgenologist (Dr. L. G. Rigler) made a diagnosis of capillary pneumonia.

The course of the disease was characterized by cyanosis, dyspnea, pain and a sensation of pressure in the chest, especially on exertion, although tachypnea was not prominent. The patient complained of weakness and perspired profusely until the nineteenth day, after which he improved. In a roentgenogram made five months later the shadows shown in figure 10 were present but diminished in density.

In this case there was evidence of early involvement of the upper part of the respiratory tract, soon followed by diffuse patchy bilateral pneumonia with disseminated areas of density and evidences of consolidation in the bases. Severe pleural pain persisted for nearly two weeks. Dyspnea, cyanosis and profuse sweating, but practically no cough or sputum, were prominent features. The leukocytes were not increased in number, and roentgenograms showed slowly resolving bilateral diffuse pneumonia.

#### SUMMARY

The strikingly similar clinical features of the cases reported suggest that the condition belongs to a disease group not conforming to influenza or the usual form of the common cold but included in an undifferentiated group of infections of the respiratory tract, often called tracheobronchitis, capillary bronchiolitis or bronchopneumonia.

*Pulmonary Symptoms.*—After several days of mild symptoms of hoarseness and sore throat, the temperature rose in each case, reached high levels, persisted with remissions for the duration of the illness and declined by lysis. In the early period in seven cases the pulse rate was slow in proportion to the fever. The temporary remission of symptoms after the first day or two of illness in cases 1, 3, 6, 8, 9 and 10 suggests that the fever may have been biphasic, a characteristic of many diseases caused by filtrable viruses, but accurate data of the first few days is lacking. The fever curves in cases 2, 7 and 9, observed from the first and second days, were not biphasic. Infection seemed to spread rapidly in some cases and more slowly in others until the trachea, bronchi and eventually the lungs were involved in a diffuse, bilateral process which persisted several weeks and was followed by a residuum which lasted several months. There was involvement of much of the smaller bronchiolar system, as manifested by dyspnea and cyanosis in each case, but evidence of consolidation was never striking. Tachypnea was not prominent. In five cases cough was distressing; it was hacking, paroxysmal or continual, but in no case was more than a slight amount of sputum raised. The respiratory rate was increased somewhat in each case but not to the degree expected from the extent of the pneumonic lesion. Cyanosis and dyspnea were noted in all cases. In cases 2 and 11 cough was minimal in spite of widespread pulmonary invasion. The fact that abnormal signs and roentgenographic shadows persisted so long in some cases suggests that the interstitial tissue was severely injured. Severe pleuritis and friction sounds were present in four of the eight cases of serious involvement, and sterile effusion took place in one.

*Nervous and Other Symptoms.*—Next to the symptoms of tracheobronchitis and pneumonia, sweating and drowsiness were most prominent. Sweating was profuse in six of the cases but not striking in case 3. Headache was present in all, but muscle pains were minimal. Photophobia was distressing in five cases. In cases 3 and 10 nervous symptoms were more severe, with stiffness of the neck, photophobia, intense headache, twitching, somnolence and disturbed reflexes sug-

gestive of meningo-encephalitis, and in case 10 the spinal fluid contained several hundred cells per cubic millimeter.

The only symptoms referable to the gastrointestinal tract were constipation, abdominal distention and a heavily coated tongue, which were present in five cases. Loss of weight was conspicuous in four cases. Early in the course of the disease in several cases constitutional symptoms predominated over those arising from the respiratory tract, as in cases 1, 2 and 9, but later the pneumonia attracted most attention.

The fever lasted from ten to forty-three days in the cases of severe involvement but usually about three weeks. Rales and roentgenographic evidence of pulmonary infiltration persisted in some cases for weeks or months afterward.

The routine laboratory data were not unusual. The urine usually gave evidence of transient febrile nephrosis. Slight secondary anemia developed. The initial leukocyte count was about normal, but initial leukopenia was present in two cases. The count usually increased during the course of the fever. The number of polymorphonuclear cells was usually increased relatively and absolutely. Blood cultures never contained bacteria, and agglutinins for other bacillary diseases were absent.

#### THE VIRUS

The failure to isolate a virus in most cases, if one was present, was probably due to the delay before attempts were made or to the weak pathogenicity of the virus for the species of animals which were inoculated. According to British investigators,<sup>3</sup> the probability of obtaining the virus of influenza diminishes rapidly after the third day. These investigators also suggest that when the virus attacks the lungs there is less of it in the upper regions of the respiratory tract.<sup>3</sup> With only two patients of the present series, who had been in close contact, were attempts to obtain a virus made as early as the fourth day of illness. From both patients Dr. Stokes and Dr. Francis obtained an unusual virus, from the nasopharyngeal washings of one and from the blood of the other. It was weakly virulent for mice and caused pneumonia and encephalitis about two weeks after inoculation. It is of interest that a somewhat similar virus was apparently obtained from a series of patients by Francis and Magill.<sup>4</sup> The virus caused meningitis and pneumonitis when inoculated in animals.

Experiments are now under way to determine whether the virus obtained from my patients was (a) actually the cause of the disease, (b) the cause of encephalitis accompanying an infection of the respiratory tract, (c) a commensal unrelated to the disease or (d) a virus accidentally encountered in the animals used in the tests. The last possibility is unlikely, since a similar virus was recovered from the same patients by two investigators working in different cities with different lots of animals. The experimental studies will be reported in detail in a later paper.

#### DIAGNOSIS

As mentioned, in three of the cases in which the signs of pneumonia were delayed, typhoid with tracheobronchitis was suspected because of the suggestive symptoms, signs and laboratory data. Pulmonary

3. Stuart-Harris and his associates,<sup>1</sup> page 104.

4. Francis, Thomas, and Magill, T. P.: An Unidentified Virus Producing Meningitis and Pneumonitis in Experimental Animals, *J. Exper. Med.* 65: 147-160 (Aug.) 1938.

tuberculosis and tularemic pneumonia were suggested in cases 9 and 11, and miliary tuberculosis was suggested in case 10. The clinical descriptions of cases 1, 8, 9 and 11, except for the absence of proof of a biphasic temperature curve, fit well with the clinical description of psittacosis, yet no biologic tests or evidence of contact infection supported this diagnosis. It was more difficult to separate the clinical features from those of influenza or influenzal pneumonia, which several other physicians believed some of the patients to have, yet it was proved that the virus of influenza was not present. Some of the clinical features were more like those of the "febrile catarrhs" described by British observers<sup>1</sup> than those of influenza, and the task now is to determine whether the disease is one member of the undifferentiated group of febrile catarrhs. It seems likely that the disease as discussed here, particularly in the age group dealt with, represents (a) the severe uncomplicated form of an otherwise mild and commonly encountered infection, (b) the visitation of a special form of virus infection in 1938 or (c) several different infections with clinical characteristics in common.

From London in 1937, Scadding<sup>5</sup> reported under the term disseminated focal pneumonia four cases of an unusual pulmonary infection, two of which were strikingly similar to my cases. They were characterized by a gradual onset, malaise, shivering, dyspnea, dry cough, marked sweating, slight leukocytosis and roentgenographic shadows of diffuse pneumonia. The disease lasted three or four weeks, and all patients but one recovered. The patient who died had bulbar encephalitis, which might be significant, considering that there was evidence of encephalitis in two of my patients and that the virus which was recovered from one was pneumonotropic and neurotropic in animals. In Scadding's patient the pulmonary lesion consisted of interstitial inflammation, slight fibrosis of the alveolar walls and edema and hemorrhage in the alveoli, changes which commonly occur with pneumonias caused by filtrable viruses.<sup>6</sup>

That it is permissible to group similar diseases together as probable entities on a clinical basis as I have done here has been shown many times in the past. Most of the infectious diseases were delineated long before their causative agents were discovered. The general behavior of the disease in my cases strongly suggests that the infection was caused by a filtrable virus and was not bacterial in origin, as discussed elsewhere.<sup>7</sup> Its similarities to the virus diseases influenza, colds and psittacosis have been mentioned. If the infection described here can eventually be proved to be an etiologic entity, the matter of naming it will arise. To avoid a name too restrictive or too indefinite it would seem best at present to call it a type of infection of the respiratory tract, perhaps type A, or type A virus pneumonia if it can be proved that the virus was the cause.

#### CONCLUSION

In a series of eight cases of an unusual, uniform, severe infection of the respiratory tract the disease was not caused by the virus of epidemic influenza or psittacosis, nor was it like other commonly described diseases. I was therefore led to regard it as a separate disease entity pending the outcome of further experimental

studies. The infection occurred in adults and began as a mild infection of the respiratory tract; this was followed by severe, diffuse, atypical pneumonia and in two cases by the symptoms of encephalitis. Dyspnea, cyanosis, hoarseness, cough without sputum, drowsiness and profuse sweating were the chief characteristics. The disease lasted several weeks. A filtrable infectious agent recovered from the nasopharynx of one patient and from the blood of another may have been etiologically related to the infection, but the evidence is incomplete. Experiments to clarify this point are under way.

### Clinical Notes, Suggestions and New Instruments

#### ACUTE YELLOW ATROPHY OF THE LIVER FOLLOWING SULFANILAMIDE MEDICATION

EDWARD W. CLINE, M.D., COLUMBIA, Mo.

As far as I know, there has been no report of a fatal case of sulfanilamide poisoning in which massive destruction of the liver cells has caused death. The report of such a case, with autopsy, therefore seems to be justified.

#### REPORT OF CASE

*History.*—R. B., a youth aged 18, a university student, seen in the clinic of the Student Health Service Jan. 22, 1938, complained of moderate nausea, vomiting and diarrhea of three days' duration. At the time of his admission he was moderately jaundiced but not cyanosed. He was admitted to the hospital with a diagnosis of acute catarrhal jaundice. After a more complete study in the hospital, the diagnosis was not changed. At this time it was learned that he had been under treatment for gonorrheal urethritis for a little more than two months and that he had been receiving sulfanilamide under the careful supervision of his physician.

His physician later supplied the prescriptions, which called for 80 grains (5.2 Gm.) the first day, 60 grains (4 Gm.) the second, 40 grains (2.6 Gm.) the third, and 20 grains (1.3 Gm.) a day thereafter until 700 grains (140 5 grain tablets, or 45 Gm.) had been taken. A period of rest from sulfanilamide therapy, lasting about two weeks, was then ordered. After this interval, a second series was started but was discontinued after three days because of gastrointestinal symptoms. From statements the patient made it was learned that he had taken sulfanilamide in excess of the prescribed dosage because huge doses controlled the urethral discharge. There was also evidence that he had taken the drug during the prescribed rest period. Unfortunately, more specific information was not obtained before the patient became irrational.

The hospital course was uneventful and afebrile, and the symptoms steadily improved. January 24 he was permitted to leave the hospital to take a final examination, but he returned January 25 with an accentuation of all his initial symptoms.

His initial treatment consisted of a fat-free diet and intravenous administrations of dextrose in saline solution. On the first day he slept almost constantly and had to be awakened for food or medication. About thirty hours after his second admission he became very restless, incoherent, irrational and disoriented. Three hundred cc. of 15 per cent dextrose solution intravenously markedly improved these symptoms. However, on the following day he again became irrational, disoriented and at times violent and noisy. At this time it was noted that the percussion boundaries of the liver were abnormally narrow. A diagnosis of acute yellow atrophy of the liver was made. Intravenous administration of dextrose solution caused little improvement this time. Vomiting became frequent and violent, and the vomitus was bile stained. On the night of the third hospital day he became extremely noisy and violent and had to be restrained. Morphine one-fourth grain (0.016 Gm.) and

5. Scadding, J. G.: Disseminated Focal Pneumonia, *Brit. M. J.* 2: 956-959 (Nov. 13) 1937.

6. Reimann, H. A.: The Pneumonias, Philadelphia, W. B. Saunders Company, 1938, chapter 15.

7. Reimann: The Pneumonias, p. 256.

scopolamine  $\frac{1}{150}$  grain (0.0004 Gm.) were given with only temporary relief; he soon relapsed into the violent stage.

During the next day he remained very restless and at times noisy and violent, needing constant restraint and large doses of sedatives (phenobarbital sodium and sodium bromide). He showed no recognition of his parents. He vomited almost everything he took by mouth, and he was incontinent of urine and feces.

January 29, the fourth hospital day, at 8 a. m., pulmonary edema developed. Four hundred cc. of blood was removed by venesection and he was placed in an oxygen tent. His condition became steadily worse, and he died at 1:55 p. m. His death was respiratory in nature, the heart beats being audible for some time after the cessation of respiration.

The temperature, which had been normal during the first hospital stay, remained so for the first two days of this stay and then rose rapidly and fluctuated between 101.4 and 104.6 F. until death.

**Laboratory Data.**—The Kahn reaction of the blood was negative. The total white blood count on admission was 7,296 with 89 per cent polymorphonuclear neutrophils; on the day before death it was 14,176 with 82 per cent neutrophils. The day before death nonprotein nitrogen of the blood was 33 mg. per hundred cubic centimeters. The icteric index was 133 on admission and 166 the day before death. The urine was essentially normal on admission but showed many casts on the day of death.

**Autopsy.**—This was performed by Dr. M. Pinson Neal approximately three hours after death. In addition to the generalized jaundiced condition of the skin and all the organs, the significant pathologic changes were in the brain, the lungs, the kidneys; the spleen and especially the liver.

The dura mater of the brain was bile stained and excessively wet. The convolutions were rather flat and the sulci filled with fluid. The blood vessels of the meninges were markedly engorged. Otherwise there were no abnormal gross or microscopic manifestations in the brain.

The lungs were wet and boggy; microscopically they showed compensatory emphysema, patchy bronchopneumonia with areas of gray hepatization and others of red hepatization, and rupture of the bronchiolar walls and peribronchiolar hemorrhage.

The spleen weighed 400 Gm. and microscopically showed hyperplastic splenitis.

The kidneys showed nephrosis of undetermined etiology.

The liver weighed 1,200 Gm. and grossly did not appear especially abnormal except for the bile staining. Microscopically it showed a massive breaking up of the liver lobules and liver cords, with separation of the remaining fragments into indiscriminate cell groups. There were areas involving two or more lobules in which not a single liver cell would be recognized as such. The liver cells that could be recognized almost uniformly showed fatty changes, with the cytoplasm containing droplets and globules of fat. Bile pigment was scanty. In some areas the only structures recognized as liver tissue were the bile capillaries. There was very little evidence of inflammatory reaction. The entire picture was one commonly seen in acute yellow atrophy.

#### COMMENT

There was no history or other indication that any drug or possibly toxic substance other than sulfanilamide had been taken by the patient. The initial diagnosis was acute catarrhal jaundice, and this diagnosis was not changed until severe toxic symptoms made their appearance.

As nearly as could be determined, no sulfanilamide was taken after the onset of the symptoms which led to his admission to the hospital. If this is correct, the fatal damage to the liver must have been accomplished by the time the symptoms began. University students, as a group, are surprisingly familiar with sulfanilamide, and unfortunately many regard it as a panacea for any infection. This case seems to give substantiation (if this is needed) to the idea that self medication with this drug is very dangerous, for here liver damage was apparently irreparable by the time any symptoms were recognizable.

University Hospital.

## Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION OF THE FOLLOWING ARTICLE AND REPORTS.

HOWARD A. CARTER, Secretary.

### THE PHYSIOLOGIC EFFECTS OF ULTRAVIOLET RADIATION

HENRY LAURENS, PH.D., LL.D.

NEW ORLEANS

The physiologic effects of ultraviolet radiation, in contrast to pathology and therapy, are difficult to grasp and to reduce to brief fundamentals.

#### SKIN

Many important effects on the body are mediated by the skin and by changes produced in it. The anti-rachitic effect occurs in the lowermost cells of the horny layer and in the prickle cells of the malpighian layer, while the production of erythema takes place in the basal cells (germinativum) of the malpighian layer and in the corium. The horny, clear and granular layers act as filters. Ergosterol and cholesterol can be activated by ultraviolet rays which pass through the epidermal layer of the skin. Blood in the superficial capillaries absorbs only a small percentage of energy incident on the skin.<sup>1</sup>

The "burn" produced by ultraviolet takes a few hours to appear and the longest wavelength that can produce it is about 3,150 angstroms.<sup>2</sup> The curve representing relative effectiveness of different wavelengths rises to a maximum at 2,967 angstroms, descends to a minimum at 2,800 angstroms, then rises again to a smaller maximum near 2,500-2,450 angstroms and extends to an undetermined shorter wavelength. Blondes are from 40 to 170 per cent more sensitive than brunets, men 20 per cent more sensitive than women. Persons between 20 and 50 are more sensitive than those younger or older. There is an average maximum sensitivity in March-April and in October-November. A person with an unstable nervous system, an overactive thyroid gland, elevated blood pressure or active tuberculosis shows increased sensitivity. The sensitivity increases at the menses—a maximum being reached on the first day of the cycle—and then declines to normal. After the second month of pregnancy the sensitivity markedly increases until the seventh, after which it diminishes somewhat, being still high at term. Increased sensitivity is correlated with thyroid hyperactivity and with increased number of open capillaries in the skin. An acid diet increases sensitivity. Salves exert a protective action, an acid salve less than an alkaline.<sup>3</sup>

The erythema reaction is used as a practical means of evaluating or appraising the ultraviolet output of lamps. So far as known there is no other biologic, physical or chemical reaction which has a similar effectiveness. It is scientifically meaningless and misleading to evaluate therapeutic effectiveness in terms of erythema response unless therapeutic effectiveness very

2. An angstrom unit of wavelength is one ten-millionth millimeter.

3. Ellinger, F.: *Biologische Grundlagen der Strahlenbehandlung*, p. 153.

closely follows it, and there is no apparent reason for assuming such a relationship. This can have no meaning unless the sole benefit of radiation therapy arises in some way from the apparent injury as shown by erythema.<sup>4</sup> About nine years ago a request came to the Council for a simple means for determining whether a lamp emits ultraviolet. The Council recommended the erythema test, but it has repeatedly and very specifically stated that the erythema test is not a measure of therapeutic effectiveness. Nevertheless, the use of the erythema reaction is of practical usefulness, since its determination serves to prevent severe burns and to safeguard against the fraudulent sale of lamps deficient in ultraviolet radiation.

Erythema shows the reactions of the "triple response"<sup>5</sup> and depends on the setting free of H-substance.<sup>6</sup> The acidity of the gastric juice increases simultaneously with its beginning.

Care should be used to avoid overexposure. Not only may a painful sunburn result but more deep-seated injury may occur, as indicated by nervousness, apprehensiveness and insomnia. Long continued exposure produces, in some individuals, various cutaneous conditions.

Erythema is followed by pigmentation. Ectodermal pigment is almost exclusively in the basal cells, occurring in the white race in the outer layers only when the skin is well tanned. In Negroes pigment is more abundant in the basal layer but there is also much pigment in the outer, including the horny, layers. The process of adaptation or protection consists in proliferation, cornification, pigmentation and changes in skin cell proteins. The shorter waves are absorbed by the horny layer (about 30 microns thick) and never reach the living cells of the epidermis. The longer waves which penetrate as far as the dermis (50-80 microns) may act on the blood in the papillae. The basal layer pigment, which increases after irradiation with wavelengths shorter than 3,150 angstroms, diminishes the amount of ultraviolet which may reach and penetrate the basal cells and thus protects the dermis from receiving too much energy. The function of skin melanin as a screen against ultraviolet is small in the white race, of more importance in the Negro and is the principal reason for his low sensitivity.<sup>7</sup>

Pigment formation and therapeutic benefit are independent, coordinate phenomena proceeding simultaneously in the same direction. Pigment formation is dependent on individual factors, race, coloring, constitution and body function. It can be used as an index in treatment. It is also a measure of adaptation, since pigment formation, horny layer thickening and chemical alterations of the skin cell proteins run parallel.

#### EYE

The cornea begins to absorb at 3,600 angstroms and transmits to between 2,950 and 3,000 angstroms, and the crystalline lens transmits to 3,060-4,190 angstroms, according to age. The vitreous transmits wavelengths

as short as 2,300 angstroms, with a broad absorption band from 2,500 to 2,800 angstroms. The lens absorbs wavelengths as short as 2,950 angstroms with no ill effects, but shorter wavelengths produce a severe ophthalmia. Sunlight is ordinarily harmless but when the ultraviolet component is increased by reflection, as from sand, water, ice or snow, it produces "snow blindness."<sup>8</sup> Glowing arcs and metals which emit energy shorter than 2,950 angstroms are injurious and special ultraviolet absorbing glasses should be worn. The damage is usually limited to conjunctivitis and blepharitis, with pricking pain and uncomfortable foreign body sensation. Edema and contraction of the lids and corneal erosion may occur. Long continued exposure to intense ultraviolet may produce functional disturbances, such as color scotomas and constriction of the peripheral field. Amblyopia and central scotoma have been noted in "snow blindness." "Eclipse blindness" is due to intense local action of infra-red rays.

It is still a question as to whether intense ultraviolet produces lenticular cataract. Many incline to the view that glass workers' cataract is due to the intense infra-red rays which interfere with the nutritional functions of the ciliary body. It is probable that the higher incidence of cataracts in workers exposed to molten glass and metals is due to increased rate of precipitation of light-denatured protein when the lens is heated above body temperature by exposure to large sources of radiant heat and when low concentrations of calcium, or other substances producing a similar effect, are present.<sup>9</sup>

Claims have been made that some persons can see wavelengths as short as 3,130 angstroms. This is due to excitation of the retina by fluorescent (longer) wavelengths. The aphakic eye sees shorter wavelengths than the normal eye.

#### BLOOD

Long continued darkness produces no marked effect as long as the diet is satisfactory. There is no such thing as "tropical anemia." The number of reds, whites and platelets may be made to increase by appropriate irradiation. Irradiation produces a lowered blood sugar, increased sugar tolerance, increased blood calcium, relative lymphocytosis and eosinophilia. In lymph an increase in protein, a decrease in sugar, an increase in calcium and an increase in cell number have been observed. A leukopenia in peripheral blood and a leukocytosis in splanchic blood has been recorded.

While irradiation with ultraviolet may have some effect on secondary anemia, this is limited and not specific and far less efficient than dietetic and drug treatment.<sup>10</sup>

Intense ultraviolet radiation may result in abnormal white blood cell counts.<sup>11</sup> There is no unequivocal evidence that ultraviolet radiation increases resistance to specific or general infection, although a relationship between sunlight and the general course and character of disease, growth and nutrition has been demonstrated.<sup>12</sup>

4. Brackett, F. S., in Cold Spring Harbor Symposia on Quantitative Biology, 1935, vol. 3, p. 266.

5. Sir Thomas Lewis in 1927 demonstrated that the response of cutaneous vessels to mechanical, electrical, thermal and chemical injury is triple. There is (1) a reddening due to capillary dilatation, (2) a mottled red flare with crenated edges, the result of arteriolar dilatation, and (3) a wheal, due to increased permeability of the minute vessels which permits the escape of fluid, closely resembling plasma in composition, into the tissue spaces.

6. Histamine when introduced into the skin produces a typical triple response, and ultraviolet rays elicit a triple response owing to the local liberation in the skin of histamine or of some closely related substance (H-substance).

12. Laurens: Physiological Effects of Radiant Energy, pp. 232, 259.

## CIRCULATION

There is evidence that sunlight and artificial radiant energy may lower blood pressure, normal and elevated.<sup>13</sup> Certain experimenters, notably Laurens and his co-workers,<sup>13</sup> appear to have demonstrated that the energy emitted by carbon arcs lowers the blood pressure of animals and human beings. Following irradiation intense enough to produce erythema the systolic blood pressure of hypertensive persons may drop an average of 17 mm. (range 2 to 41), the diastolic of 7 mm. (range 2 to 20). The cardiac output (volume per minute) usually increases when the blood pressure is lowered. The precise mechanism involved in the apparent fall in blood pressure obtained under these experimental conditions may possibly be due to factors other than the ultraviolet rays themselves. From a clinical standpoint the claim that ultraviolet rays reduce blood pressure does not appear to have been sufficiently established by the majority of those who have had long experience with natural or artificial heliotherapy to command acceptance. Most of them feel that, while exposure of the entire body to ultraviolet rays may produce some reduction in blood pressure in certain individuals, this reduction cannot be depended on and is too slight and inconstant to be of clinical value.<sup>14</sup>

The lowered blood pressure of persons living in the tropics is the result of the action of a number of characteristics, racial, mode of life, meteorological conditions and their changes and cannot be correlated with the quantity and quality of radiation.

Intense irradiation may markedly accelerate the heart, but this is not specific for ultraviolet. The pulse may become "fuller" and "stronger" during and following a course of irradiations, correlated with increased minute volume.

## METABOLISM

Irradiation of moderate intensity increases endogenous nitrogen metabolism. Residual nitrogen is usually diminished. The excretion of uric acid is said to increase, giving support to the use of ultraviolet in the treatment of gout. Ultraviolet irradiation may double the fat content of the blood, cholesterol increasing by 30 per cent.

The blood sugar of normal men is not influenced to any extent by ultraviolet irradiation, while in some persons with diabetes the blood sugar may be temporarily diminished. The decrease is probably due to increased excretion of insulin. The diminution in blood sugar may be accompanied by increased storage of glycogen in the heart, liver and muscle.<sup>15</sup>

Irradiation of lactating women may increase to some extent the quantity and antirachitic potency of the milk.<sup>16</sup>

The effect of ultraviolet irradiation on respiration is to make it easier, deeper and less frequent. Total ventilation per minute remains constant.<sup>17</sup> It has been generally accepted that basal metabolism is not influenced by ultraviolet irradiation. When an increase in metabolic rate is observed upon insulating the nude body it is due preeminently to the cooling effect of the

moving air. If the air temperature is high with little or no air movement, the chemical heat regulating mechanism is brought into action and the metabolic rate diminishes. Lehmann and Szakáll<sup>18</sup> have demonstrated that brief, intense irradiation, resulting in erythema, leads to an increase in metabolic rate lasting as long as twenty-two hours. Repeated irradiation produces a diminution of between 10 and 15 per cent in basal rate, still demonstrable from three to four weeks after the last irradiation. Parallel with this diminution there is an increased respiratory quotient, from 0.75 to 0.85 to more than 1.0, indicating a preferential combustion of carbohydrate.<sup>19</sup> Ultraviolet irradiation exerts a glycogen storing effect, preventing the lowering of the respiratory quotient after muscular exercise, which lowering is due to glycogen impoverishment.

According to Holtz and Wölpert,<sup>20</sup> ultraviolet irradiation prevents clinical evidence of scurvy in guinea pigs and man due to increased metabolic rate.

## GROWTH

Practically all of the attempts to show effects of light on normal growth processes of man and animals have been negative. Animals will grow as well in darkness as in light if the diet is complete. A rise in the growth curve (height and weight) of children is reported in the spring (March to June), a drop during the hot summer months, a second rise in autumn (September to December) and a depression in winter (December to February).<sup>21</sup> Frank<sup>22</sup> found no apparent correlation with temperature, precipitation or sunlight. Exposure to artificial sources, emitting both short and long waves, produces small increases in height, regarded by Nylin<sup>23</sup> as significant. The increase in weight was at a minimum when the increase in height was maximum, and when there was no irradiation the increase in height was minimum while increase in weight was maximum. Growth curves of Australian infants show that seasonal differences are not large, regular or consistent.<sup>24</sup>

A gain in weight of rabbits living under laboratory conditions and exposed to neon light has been demonstrated.<sup>25</sup> Most of the energy emitted by the lamps was between 5,800 and 7,600 angstroms, the ultraviolet components extending from 3,370 to 3,620 angstroms, the strongest rays being between 3,460 and 3,480 angstroms. The chick requires the ultraviolet as well as the longer portion of the solar spectrum in order to grow normally. Cod liver oil, however, is able to compensate for deficiency in any part of the spectrum.<sup>26</sup> The production and the fertility of eggs are similarly influenced.

Goldblatt and Soames, Steenbock and Black and Hume<sup>27</sup> demonstrated that a growth promoting factor could be induced in rats in vivo. If rats are kept on a diet deficient in growth promoting factors until they cease gaining weight for about four weeks, their livers, fed to other rats, do not possess growth promoting factors. But if, after complete stoppage of growth, the

rats are irradiated with a quartz mercury lamp for a few weeks their livers acquire the property of stimulating for a short while the gain in weight of rats that have ceased growing on a diet deficient in growth promoting factors. These results are due to the activation of vitamin D which is stored in the liver. This was the first actual demonstration that inert provitamin D could be "activated" into vitamin D.

Ultraviolet has no influence on the activity of the thyroid.<sup>28</sup> The goiter producing power of cabbage is reported to be increased by ultraviolet irradiation.

#### MINERAL METABOLISM

Ultraviolet irradiation with wavelengths shorter than 3,130 (particularly 2,967 angstroms) exerts an influence on calcium and phosphorus even when the diet is adequate.<sup>29</sup> But of even greater importance from the standpoint of protection against dietary deficiencies is the action of ultraviolet radiation in rectifying partial lack of the components necessary for proper calcification of bone and teeth.<sup>30</sup>

Ultraviolet irradiation gives rise, from the provitamins in the skin, to vitamin D, the agent which promotes normal calcium anabolism and retention of phosphorus. Therefore it may prevent and cure rickets, adult as well as infantile, promote growth and prevent excessive loss of lime from the body. It apparently does not influence the healing of fractures.<sup>31</sup> It is necessary not only for the development of teeth but for their protection later in life. In dental caries, rickets is only one of several etiologic factors. Enamel is an epithelial tissue, while bone and dentine are connective tissues.<sup>32</sup>

Ultraviolet irradiation may be used in the treatment of infantile tetany, a symptom complex occurring in rickets when the blood calcium is low. The treatment of choice is a combination of a calcium salt (lactate or gluconate), a diet low in phosphate and optimal vitamin D.<sup>33</sup> Latent tetany may become manifest when rachitic infants are irradiated if sufficient calcium is not available, owing to the suddenly increased mobilization and deposition of calcium in the growing bones.

Irradiation of normal rabbits may produce a marked hypertrophy of the external parathyroid which may represent an increased factor of safety to protect the calcium level under conditions of emergency. Keeping chicks in darkness gives rise to a hyperplasia which may be prevented by ultraviolet irradiation. While irradiation of parathyroidectomized animals and man will keep them free from tetany, vitamin D itself is far more efficient.

When an animal is irradiated, its skin, liver, fat and muscle become antirachitically active.<sup>34</sup> Ultraviolet radiation forms vitamin D either in the cells of the living organism or in its foodstuffs. The action of a foodstuff artificially rendered antirachitic by irradiation is qualitatively the same as the action of a naturally occurring

foodstuff containing the antirachitic factor. Slight qualitative differences may exist depending on whether the foodstuff is of animal or vegetable origin.<sup>35</sup> Direct exposure of the skin to ultraviolet rays from the sun or from artificial sources results in the formation of vitamin D within the organism, but the Council cannot recognize statements or implications that vitamin D has all the beneficial effects of exposure to sunshine. Not only have various foodstuffs been irradiated to increase their content of vitamin D but there has been a tendency to add preformed vitamin D to foods.<sup>36</sup> Milk is poor in vitamin D but is an excellent source of calcium and phosphorus. The Council on Foods therefore considers that, of all the common foods available, milk is most suitable as a carrier of vitamin D. The Council has recently made the decision that for the present milk is the only common food which will be considered for acceptance when fortified with vitamin D. One of the methods used to impart antirachitic properties to accepted vitamin D milks is irradiation with ultraviolet shorter than 3,130 angstroms.

Activation depends on the same wavelengths effective directly in the cure and prevention of rickets.

Vitamin D in some way regulates the passage of calcium and phosphorus across the intestinal wall. It exerts its action by raising the blood calcium and/or phosphate. This is associated usually with an increased net absorption from the intestine, though under certain circumstances the bones may provide the calcium and phosphate. The net retention of the animal as a whole is the resultant of two opposing factors: (1) increased absorption from the intestine or diminished excretion to it and (2) increased excretion by the kidney. As the dosage of vitamin D becomes larger, the second factor overtakes the first.

It has been asserted that vitamin D acts through stimulating the parathyroid glands.<sup>37</sup> But the effects of irradiated ergosterol and of parathyroid extract on the plasma phosphatase, on the blood and urine chemistry and on the microscopic appearance and chemical composition of the bones are dissimilar. Parathyroid extract, although it relieves the tetany associated with rickets in infants, fails to induce healing in the rachitic metaphysis and may actually retard it, whereas vitamin D promotes calcification in the metaphysis and in so doing may even temporarily produce hypocalcemia and tetany unless a sufficient amount of calcium is provided. The resemblances between the effects of vitamin D in excess on a diet poor in calcium and those produced by excess of the parathyroid hormone are fortuitous. Similarly the effects of excess vitamin D and of parathyroidectomy on blood calcium are in opposite directions but not connected by any causal relationship.<sup>38</sup> Vitamin D given to rickety animals increases the adsorbable fractions of calcium and the total adsorbable phosphorus. It seems to be the diffusible, adsorbable, calcium phosphorus complex which provides the substance for the calcification of bone. Parathyroid hormone, unlike vitamin D, increases the ion-containing fractions.

Vitamin D occurs in relatively few foodstuffs, though it can be developed in some by appropriate irradiation. It rarely, if ever, occurs in living plants. Dead plant tissue by insolation may acquire slight potency. In the animal kingdom vitamin D is widespread but is abundant only in fish. Its origin is obscure; some of it may originate by synthesis. Higher animals lack the power to synthesize vitamin D and their requirements are met by ingesting it or by exposing the body surface to sunlight. In all cases, except possibly fish, the ultimate origin of vitamin D is traceable to sterols activated by ultraviolet rays.<sup>39</sup>

#### PHOTODYNAMIC OR OPTICAL SENSITIZATION; PATHOLOGY

It is possible to sensitize living cells, like photographic plates; and thus produce abnormal conditions in which light or luminous rays and longer ultraviolet rays are as active as the shorter ultraviolet.<sup>40</sup> The effective wavelengths are those absorbed by the sensitizer. Sensitization occurs at 4,900-5,800, 3,650-3,130 and 2,500 angstroms. The sensitizers are exogenous, taken in with the food, and endogenous, arising within the organism. Most sensitizing substances are fluorescent, but fluorescence is not the cause. Ultraviolet effects can occur either in the presence or in the absence of oxygen, but the photodynamic effects occur only in its presence. Among photodynamic sensitizers are erythrosin, rose bengal, rhodamin, anthracene derivatives, acridine dyes, methylene blue, quinine, chlorophyll, hypericin and the porphyrins.

Continued and prolonged exposure to sunlight or to the energy of artificial sources containing much ultraviolet may cause systemic disturbances as well as inflammatory and degenerative changes in the skin. The systemic disturbances are not understood, but deaths of infants following short exposure have been reported and severe reactions in adults.<sup>41</sup>

The porphyrins may sometimes sensitize, as in lead poisoning,<sup>42</sup> but even when present in large amounts, as in sulfonal and trional poisoning, they may not. Light sensitivity may even be reduced when porphyrins are present in large quantities, as in hydroa vacciniforme, which would thus seem to be a "climate disease" in which abnormal metabolism of porphyrins is the underlying factor and the combined working of ultraviolet and minor injury (in the form of increased air movement in the spring) the releasing factor. Again, porphyria may not be present in some cases of hydroa vacciniforme and in these instances there may be hypersensitivity to repeated ultraviolet irradiations as well as normal sensitivity. Hydroa vacciniforme is probably a symptom found in numerous conditions.<sup>43</sup> It is further possible that porphyrins play no part in light sensitivity. They may represent products of skin injury and be a result rather than a cause of dermal sensitization. Porphyrinuria may be the result rather than the

cause of the disease, and the excretion of porphyrin is not a constant manifestation of this group of diseases.<sup>44</sup>

Reports on treatment with photodyn and with sulfanilamide indicate that in some persons unpleasant results of photosensitivity may occur.<sup>45</sup>

Urticaria solare may occur after short exposure to sunlight. It is accompanied by immediate and severe erythema, edema and itching. Normal erythema is produced by ultraviolet radiation of wavelengths shorter than 3,150 angstroms. It is a delayed reaction, a "triple response," appearing an hour or more after moderate exposures, and is followed later by pigmentation. Both erythema and pigmentation are independent of oxygen. Urticaria solare manifests itself as a "triple response" and is produced by luminous violet and blue rays (from 3,900 to 5,300 angstroms). It is not followed by pigmentation and is independent of oxygen. Photodynamic "triple response," produced by intradermally injecting rose bengal and hematoporphyrin, is similar in appearance to urticaria solare and is produced by the wavelengths absorbed by the particular sensitizer. The response is immediate. It is followed by pigmentation and does not occur in the absence of oxygen. The mechanism of the urticarial response includes a photochemical reaction not markedly affected by temperature and a thermal reaction greatly modified by changes in temperature. The latter is probably due to the action of the H-like substance on the small vessels of the skin. The photosensitizer is a carotenoid pigment.<sup>46</sup>

The relation of ultraviolet to pellagra is difficult to evaluate.<sup>47</sup> The clinical impression that sunlight is harmful to the pellagrins has been confirmed again by Smith and Ruffin,<sup>48</sup> according to whom the seasonal incidence of pellagra is conditioned by the degree of dietary deficiency and the intensity of the solar radiation. Exposure of a susceptible subject, who has been subsisting on a deficient diet, to the sun's rays precipitates the acute manifestations of pellagra. Pellagrous lesions, however, occur in the absence of sunlight and they may heal in the presence of exposure to direct sunlight or to ultraviolet radiation. Spies<sup>49</sup> suggests that pellagra is a systemic condition which in itself is the real cause of pellagrous dermatitis and not exposure to the rays of the sun. Under conditions sunlight may act as an irritant and precipitate cutaneous lesions. But any kind of irritant may predispose an area to localization of the dermatitis, the absence of which, however, indicates little as to the cure of the disease. Porphyrinuria in pellagra has been described.<sup>50</sup>

Repeated irritation by ultraviolet rays can cause chronic lesions, which may be precancerous, such as

keratosis senilis and xeroderma pigmentosum.<sup>51</sup> It is an open question as to whether xeroderma pigmentosum and skin cancer are really associated with photodynamic action.<sup>52</sup> Roffo<sup>53</sup> believes that in the carcinogenic production of skin cancer by ultraviolet the photodynamic action of cholesterol plays the most important part. The photo-activity is due to the emanation of hydrogen peroxide or similar products. Körbler<sup>54</sup> does not believe that the frequency of skin cancer is due solely to exposure to strong sunlight, although it may result in sensitization due to local increase in porphyrin.<sup>55</sup>

The action of radiation is paradoxical in this regard. If the cells of the basal layer of the skin receive an excessive quantity of radiant energy the two protective processes of cornification and pigmentation become abnormally great (hyperkeratosis and hyperpigmentation) and a third degenerative process starts. People lacking in pigment or much exposed to ultraviolet rays show the highest percentage of skin cancer. The developing neoplasm occurs in the place of greatest proliferation, beginning in a wartlike hyperkeratosis, a precancerous change. A cancer develops from a precancerous lesion not only as a result of a continuation of the initial insult but as a result of any continued trauma. Thus ultraviolet rays do not cause cancer in themselves. They produce characteristic cell changes leading to precancerous lesions in the skin. Any irritation, including continually and excessively applied ultraviolet rays, can cause the precancerous change to become malignant.<sup>56</sup>

#### BACTERIA

Almost all bacteria may be killed or attenuated by ultraviolet rays, but there is considerable variation in the rapidity of their destruction. Those which live in the animal body are most easily affected. Those living free in nature adapt themselves to the action of sunlight and so become relatively resistant to irradiation. Direct sunlight is a powerful germicide for all except a limited number of species like the thio-, or sulfur, bacteria, which utilize sunlight for metabolic processes.<sup>57</sup>

There is general similarity between absorption curves and the reciprocals of curves for incident bactericidal energy. The curves rise rapidly from low levels beyond 3,000 angstroms to a maximum between 2,600 and 2,700 angstroms, then drop to a minimum near 2,400 angstroms and rise again toward a limit beyond the range of experimental observation. The reciprocal of the bactericidal curves matches the absorption curves of certain nucleoprotein derivatives, cytosin, thymine and uracil, more closely than those of various amino acids such as tyrosine, tryptophan or phenylalanine.

The curves expressing bactericidal effect are quite similar for all bacteria but some are more sensitive than others. Beginning with the diphtheria bacillus the effect

increases for *B. coli*, staphylococci and cholera, culminating with typhus. Tubercle bacilli capable of growth disappear at the earliest in two hours and at the latest in five hours when exposed to sunlight.

Bactericidal action is perhaps of only theoretical interest because the action of ultraviolet is effective only in very thin layers, and therefore a therapeutic action can occur only in the most superficial infections and with strong dosage. The use of ultraviolet radiation for the elimination of bacteria in drinking water has received some attention, but insufficient evidence is available to recommend this as a safe process for sterilization. More general use has been made in partial sterilization of water in swimming pools. Here again the evidence is not conclusive. Ultraviolet rays have been used in the diagnosis of ringworm and mycotic infections of the skin. Bacterial cultures may be differentiated by means of fluorescence in ultraviolet rays under certain special conditions.<sup>58</sup>

Wells and his co-workers<sup>59</sup> developed an apparatus to spray organisms into the air and another to centrifuge the air so as to concentrate bacteria and viruses contained in them. They studied the length of time during which droplets of varying sizes containing bacteria remain suspended in the air and tested the viability of floating organisms. Irradiation with a quartz mercury vapor lamp was found to be the most effective measure to sterilize air. Air contaminated with known bacteria was passed at definite distances through the rays. Those which divide in one plane, such as streptococci and pneumococci, were easily destroyed, but the outer layers of cocci which grow in clumps protected the inner ones from the rays. The virus of influenza was easily destroyed. Hart<sup>60</sup> has demonstrated that with bactericidal radiant energy operating room infections are greatly reduced, postoperative temperature in supposedly clean cases is lower and of shorter duration, there is better healing, and the patient has less postoperative discomfort.

Toxins as a rule are not very photostable, while antitoxins are resistant to the action of ultraviolet energy.<sup>61</sup> A comparison of the effects of ultraviolet on vaccine virus and on *Staphylococcus aureus* shows that energy sufficient to inactivate the virus completely kills all the staphylococci. Skin repeatedly exposed to ultraviolet rays is less susceptible to the action of vaccine virus than is nonirradiated skin. The incident energies (between 2,380 and 3,020 angstroms) necessary to kill *Staphylococcus aureus* and to inactivate its homologous bacteriophage run strictly parallel, indicating that in the two instances the same organic structures are absorbing the radiations.<sup>62</sup>

The inactivation of the virus of tobacco mosaic is confined to wavelengths shorter than 3,100 angstroms and the energy required to produce any perceptible effect at this wavelength is more than 100 times that necessary at 2,652 angstroms. The energy values representing 100 per cent killing of *Serratia marescens* are far below the values having any measurable effect on the virus. The wavelength of maximum effect is at 2,652 angstroms. The resistance ratio of virus to bacteria is 200:1. In a comparison of the relative resis-

tance of *B. subtilis* (vegetative and spore forms) and of *B. megatherium* (spore form) as compared with the resistance of *S. marescens* and the virus of tobacco mosaic to ultraviolet irradiation, the curves for spore and vegetative stages are generally conformable. Some spores (*B. megatherium*) are more resistant than others (*B. subtilis*). The resistance of the virus is so much greater than the resistance of spore stages as to be of a different order of magnitude.<sup>63</sup> Exposure to ultraviolet rays inactivates poliomyelitis virus.<sup>64</sup> Diphtheria toxin is destroyed by ultraviolet irradiation and can be sensitized to light. Tetanus toxin keeps less well in light than in the dark and can be shown to be inactivated by ultraviolet rays and by light when photodynamically sensitized.<sup>65</sup>

Both amboceptor and complement can be killed by ultraviolet, the extent of change depending on the albumin content of the serum and the concentration of antibody.<sup>65</sup> Serum complement is much more sensitive to irradiation than the b-lysin of serum or the bactericidal substances of leukocytes.<sup>66</sup> The immunizing power of bacteria, as measured by the agglutinin titer of injected rabbits, decreases considerably when the bacteria are intensively irradiated with ultraviolet rays.<sup>67</sup> Bacteria, bacteriophages and viruses are readily sensitized by photodynamic substances, particularly eosin and methylene blue.<sup>68</sup> Most of the properties of venoms are weakened or completely inactivated by irradiation. The venoms of cobra, daboia and rattlesnake may be photodynamically inactivated.<sup>69</sup>

#### PROTOZOA

The lethal effect on *Paramecium micromultinucleata* increases rapidly for wavelengths shorter than 3,000 angstroms and reaches a maximum at 2,650 angstroms, from which it diminishes for shorter wavelengths.<sup>70</sup> According to Giese and Leighton,<sup>71</sup> 2,654, 2,804 and 3,025 angstroms are about equally effective; 2,537 angstroms is less efficient. Swann and del Rosario<sup>72</sup> found that 2,536 and 2,894 killed *Euglena* readily, while 3,132 and 3,654 had practically no effect.

#### PROTEINS

Irradiation of solutions of proteins produces several effects, including shift in H ion concentration, denaturation, coagulation and increased filtering capacity for ultraviolet rays between 4,000 and 2,670.<sup>73</sup> The coagulation of isoelectric egg albumin solutions on exposure to ultraviolet rays involves three processes: (1) light denaturation of the molecule, (2) a reaction between the light denatured molecule and water, and (3) flocculation on moderate heating of the denatured molecules to form a coagulum.<sup>74</sup> Physiologic applications of the

changes produced in proteins and amino acids by irradiation include the production of erythema, coagulation of lens protein, and biologic oxidations and reductions.

#### FERMENTS

Ferments (enzymes) can be stimulated to increased activity, inhibited or destroyed, depending on the wavelength and intensity of the energy and the duration of exposure.<sup>75</sup>

The ultraviolet absorption spectrum of Northrup's pure crystalline pepsin bears a general resemblance to the absorption spectrums for urease and tyrosine. The absorption band is maximum for 2,750-2,800 angstroms and minimum near 2,500 angstroms. Tests of the rate of inactivation by different bands of ultraviolet, in relation to the absorbed energy, indicate that the destruction spectrum of the enzyme agrees essentially with its absorption spectrum and is similar to that of urease.<sup>76</sup>

The absorption curves of yeast are similar to those of certain enzymes and of nucleoprotein derivatives. The lethal spectrum of yeast in the location of its energy peaks on the wavelength scale resembles the absorption curve of the pyrimidine bases of nucleic acid, cytosin and uracil.<sup>77</sup> Light retards fermentation but ultraviolet rays markedly accelerate it.<sup>78</sup>

Nicotine is darkened and decomposed (oxidized) by ultraviolet rays and loses its vasoconstricting power by destruction of the pyrrolidine ring.<sup>79</sup> Epinephrine solutions are oxidized and lose all normal actions. Appropriate irradiation of solutions of synephrin salts increases their action, while overirradiation destroys their activity.<sup>80</sup> Ultraviolet radiation does not increase the yield of digitalis glucosides.<sup>81</sup>

#### MODE OF ACTION

Physiologic effects have their origin in photochemical reactions produced when the energy is absorbed. The effect is physical, then chemical, and finally biologic.<sup>82</sup>

Photochemical reactions are initiated by a change in electron configuration and velocity. If the incident energy is short enough it will produce vibrations in the electrons, which will be activated. These may then be ejected and the molecule thus ionized; or they may be displaced to an outer orbit, and the atom or molecule activated. Photoelectric phenomena are thus at the basis of all the subsequent reactions. The pathologic action of radiation may be considered as the result of upsetting the electronic configuration so that the proteins attain an isoelectric state and coagulate (aggregation). The nucleus of the cell is the chief point of injury.

When a solution of albumin is irradiated in an atmosphere of nitrogen there arises a reversibly oxidizable substance. The irradiated albumin gives the sulfhydryl reaction and it is suggested that when the skin is irradiated there arises in it a substance of the nature and with the functions of sulfhydryl bodies.<sup>83</sup> Reversible redox systems (glutathione and other SH substances) play important parts in cell function.<sup>84</sup>

Ultraviolet radiation causes an increase in permeability, liquefaction of the main mass of protoplasm and then coagulation.<sup>85</sup> The primary biologic process is on the large protein molecule and the problem concerns the action on the colloidal systems of the living cell. The effect is a photochemical one, and when there is a photochemical change or decomposition there is a change in the electrical charge of the colloids.<sup>86</sup>

Ultraviolet rays stimulate the basal epidermal cells, arousing them to increased activity and quickened metabolism, so that they set free, in increased amounts, the products of their metabolism. Cellular injury and degeneration, with the consequent setting free of cell decomposition products, may produce beneficial or harmful effects according to the amount set free. The cell products may be (1) the result of increased activity on the part of the basal cell layer of the skin, (2) the result of damage and degeneration or (3) "activated" substances. Substances are given off which, among other things, result in cutaneous hyperemia. These are absorbed subepidermally, are transported away and act on various distant parts of the body. Too great an effect produces harm in normal and in hypersensitive persons. Too intense action, as indicated by an excessive burn, harms or kills the basal cells so that they may give off, if not abnormal chemical derivatives, excessive amounts of normal substances. Ultraviolet irradiation is shock treatment and its value depends on the individual's reaction to it. The dosage must therefore be gaged to the individual.

### LIEBEL-FLARSHEIM ULTRA SHORT WAVE GENERATOR, MODEL SW-400, ACCEPTABLE

Manufacturer: The Liebel-Flarsheim Company, 303 West Third Street, Cincinnati.

The Liebel-Flarsheim SW-400 Ultra Short Wave Generator is recommended for medical use. It is a cabinet model featuring the air-spaced plate technic according to the manufacturer. The electrode arms are counterbalanced, readily adjustable and self retaining without bracing because of frictioned joints. Horizontal and vertical adjustment of the arms is possible. The disks may be raised even higher by hand grips. Two sizes of air-spaced plates, pad and cuff electrodes are included in standard equipment, while a small localizing plate and inductance coil are available accessory equipment. This model may also be used with official electrodes. The unit is finished in walnut and weighs approximately 164 pounds uncrated.

Liebel-Flarsheim  
Ultra Short Wave  
Generator, Model  
SW-400.

A tuned plate, tuned grid circuit is utilized employing two oscillator tubes and two rectifier tubes. The wavelength is approximately 6 meters. The patient's circuit is inductively coupled to the oscillator and a variable condenser is included in the patient's circuit for resonating it with the other circuit. Power input is approximately 1,150 watts. Energy output was measured both by the calorimeter method and by the photoelectric cell and lamp load method, indicating 430 watts respectively. The firm limits its claim to 400 watts output. The temperature rise of the outside of the transformer, after the machine had been operated for two hours at full load, was approximately 38 C. There is a four point power control and an output adjuster. Line filters are to be installed to prevent radio interference.

85. Heilbrunn and Mazia, in Duggar: Biological Effects of Radiation 1: 625, 1936. Ellinger, F.: Strahlentherapie 58: 464, 1937; Nature 138: 1014, 1936.

86. Ellinger: Biologische Grundlagen der Strahlenbehandlung, p. 210. Kartschagin, W. A., and Warschauer, G. S.: Strahlentherapie 40: 174, 1931.

In order to substantiate heating claims made for the unit, the firm submitted the following data: Temperature measurements were made with thermocouples inserted through a cannula into the anterior portion of the thigh to a depth of approximately 2 inches in the quadriceps extensor muscle (for the deep muscle test) and to approximately one-eighth inch for the subcutaneous test. Before the recordings were made, all the thermocouples were carefully checked and the galvanometers calibrated throughout the range of temperatures under consideration.

Schematic diagram.

All treatments were given to the patient's tolerance and a description of the technics employed together with the results of these tests are recorded here:

**Air-Spaced Technic.**—Two small 6 inch disks were applied in a plane parallel to the anterior portion of the thigh. The center of the lower disk was approximately 4 inches above the knee cap, the center of the upper disk approximately 6½ inches above the center of the lower. Both were spaced approximately 1 inch from the patient's skin. Thermocouples were inserted as previously described at the midpoint between the proximal edges of the disks. Temperatures of the skin were recorded at a point on the skin adjacent to the thermocouples. The averages of temperatures for six tests are given in table 1.

**Inductance Cable Technic.**—Six turns of the inductance cable were wrapped round the thigh with approximately 1 inch of turkish toweling beneath for spacing. Three turns were taken

high on the thigh, then approximately 4 inches of spacing was allowed and three more turns were taken at that point. The average temperatures for six tests are given in table 2.

**Cuff Technic.**—Two cuff electrodes with two one-fourth inch felt spacers and some additional turkish toweling to a total thickness of about 1½ inches were wrapped round the thigh with about 4 inches space between the proximal edges. The thermocouples were inserted at the midpoint. Temperature rises were recorded as in table 3.

On all these tests treatment was continued for twenty minutes with recordings made at five minute intervals.

The firm submitted tests performed by a qualified investigator as evidence to show the ability of the unit to supply sufficient heat for orificial application. A Chapman electrode was used in the observations specially drilled out so that a thermometer could be passed through and brought into actual contact with the cervical tissue so that the temperature of the cervix, rather than that of the inner portion of the electrode, would be

TABLE 4.—Average Temperatures for Six Sets of Observations, Orificial Technic

30	110.0

registered. The orificial applicator was connected to the left hand pad terminal of the machine. For a return path, the large air-spaced plate was connected to the right hand terminal and the plate was placed about 4 inches above the abdominal area. Temperatures were taken at five, ten, twenty and thirty minute intervals. Six such sets of tests were made. The averages are given in table 4.

The unit was tried out in a clinic acceptable to the Council and found to give satisfactory service.

In view of the foregoing report, the Council on Physical Therapy voted to accept the Liebel-Flarsheim SW-400 Ultra Short Wave Unit for inclusion in its list of accepted devices

### FISCHER SHORT WAVE APPARATUS, MODEL PC, ACCEPTABLE

Manufacturer: H. G. Fischer & Co., 2324 Wabansia Avenue, Chicago.

The Fischer Short Wave Apparatus, Model PC, is recommended for medical and surgical uses. It is available as either a cabinet or a portable model with either 6 or 12 meter wavelength. The portable unit comes in a keratol covered carrying case with hand grips. This may be slipped into the cabinet housing. The latter comes in two-tone walnut and bird's-eye maple or in plain ivory. Short wave applications may be made with cuff or pad electrodes as well as with the inductance cable.

Fischer Short Wave Apparatus,  
Model PC.

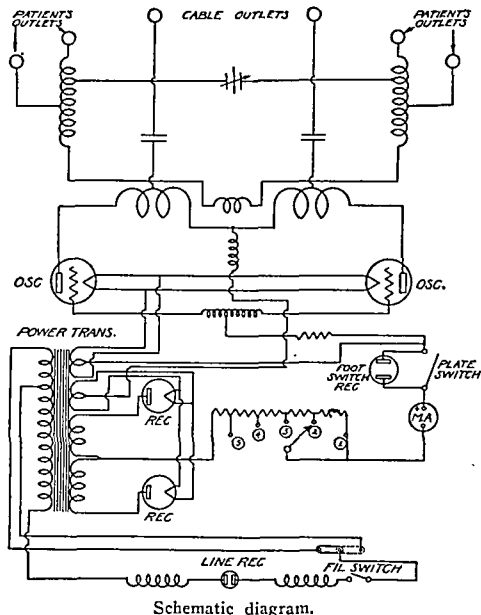

This is a four tube unit with two rectifier tubes and two oscillator tubes. It is wired to force each tube to carry its proper load. Both models have a slightly higher wavelength with cable applications. The 6 meter unit requires a power input of approximately 650 watts and has an approximate output of 260 watts as measured by the photometric method. The transformer temperature when the unit is operated at full load is approximately 182 F.

Cabinet temperatures taken at the top and the base of the cabinet are 151 and 115 F. respectively.

A power input of approximately 750 watts is required with the 12 meter apparatus. With this unit the power output as measured by lamp load and the photometric cell method is approximately 300 watts. The transformer temperature of the apparatus when operated at full load is approximately 180 F. Temperature rises inside the cabinet at top and bottom respectively are 150 and 113 F. Radio interference has been reduced to a minimum by the use of radio frequency chokes in the power supply circuit.

In order to substantiate heating claims made for the unit, the manufacturer submitted tests performed by a reliable investigator. Four male subjects whose weight ranged from 145 to

210 pounds were used in making twenty-four tests. The technical procedure for making the tests was that outlined by the Council on Physical Therapy. The results are given in the accompanying tables.

Schematic diagram.

The following technics were used in obtaining the results recorded:

(a) Cuffs  $3\frac{3}{4}$  by 32 inches and  $3\frac{1}{4}$  by 24 inches. Three-fourths inch spacing consisting of one layer of toweling. Plate current varied from 300 to 320 milliamperes. Cuffs  $7\frac{1}{2}$  inches center to center and equidistant from cannula.

(b) Four turns of cable around the thigh. Varied from 7 to 8 inches over all. Three-fourths inch spacing consisting of one layer of one-fourth inch felt and one layer of toweling. Plate current varied from 290 to 380 milliamperes.

#### The Fischer 6 Meter Short Wave Apparatus, Model PC

(a) Average of six observations, cuff technic:			
Deep Muscle		Oral	
Initial	Final	Initial	Final
99.5	106.8	98.3	98.8
(b) Average of six observations, inductance coil technic:			
Deep Muscle		Oral	
Initial	Final	Initial	Final
99.4	107.7	98.3	98.8

#### The Fischer 12 Meter Short Wave Apparatus, Model PC

(c) Average of six observations, cuff technic:			
Deep Muscle		Oral	
Initial	Final	Initial	Final
99.5	108.0	98.4	98.9
(d) Average of six observations, inductance coil technic:			
Deep Muscle		Oral	
Initial	Final	Initial	Final
99.5	107.5	98.7	99.0

(c) Two cuffs,  $3\frac{1}{2}$  by 24 inches and 4 by 32 inches. Three-fourths inch spacing consisting of one layer of one-fourth inch felt and one layer of toweling. Plate current varied from 280 to 325 milliamperes. Cuffs varied from 7 to  $8\frac{1}{2}$  inches center to center and were equidistant from the cannula.

(d) Four turns of the cable about the thigh. Varied from 7 to 8 inches over all. Three-fourths inch spacing consisting of one layer of one-fourth inch felt and one layer of toweling. Plate current varied from 260 to 200 milliamperes.

Both models were investigated clinically by a competent physician, who reported that they rendered satisfactory service.

In view of the foregoing report, the Council on Physical Therapy voted to include the Fischer Short Wave Apparatus, Model PC, in its list of accepted devices.

## CORONARY OCCLUSION WITHOUT PAIN

In a recent communication Gorham and Martin<sup>1</sup> point out that the incidence of coronary occlusion and cardiac infarction without pain is much higher than has been heretofore appreciated. They have analyzed 100 cases in which necropsy was performed. Forty-two of these patients suffered a fatal attack which was not accompanied by pain, while fifty-eight complained of pain of varying location, intensity and duration. Coronary occlusion was the primary cause of death in eighty of the cases, definitely contributory in fifteen and probable in five. At necropsy gross infarction of the myocardium measuring more than 1 cc. in diameter was found in every case, as well as sclerotic changes in the coronary arteries. Nineteen per cent of the patients in the group without pain gave a history of definite anginal pain previous to the final attack. A comparison of the two groups brought out that patients in the group without pain tended to be older than those in the group with pain, that the peak of mortality for the males is a decade earlier than for the females, that a history of preceding attacks of anginal pain and of hypertension is less common, that dyspnea is a prominent symptom and that a pericardial friction rub is rarely heard. Old infarctions, with absence of actual thrombosis and pericarditis, are more frequent. Pain was present in every one of fifteen patients who showed a combination of actual thrombosis of the coronary artery and acute infarction. However, a combination of fibrotic narrowing of a coronary artery without actual thrombosis, plus an old infarction and absence of pericarditis, was not accompanied by pain in twelve of seventeen cases (70 per cent). Wearn reported 53 per cent, Davis 40 per cent, Bruenn, Turner and Levy 61 per cent and Saphir and his associates 38 per cent of cases in which there was coronary occlusion and infarction without a preceding attack of pain. Kudrin found fifty cases with a history of anginal pain among 500 instances of sclerosis of the coronary artery found by him post mortem.

1. Gorham, L. W., and Martin, S. J.: Coronary Occlusion With and Without Pain: Analysis of 100 Cases in Which Autopsy was Done with Reference to the Tension Factor in Cardiac Pain, *Arch. Int. Med.* 62: 821 (Nov.) 1938.

Anginal symptoms were present in only eleven of thirty-four cases of coronary stenosis and in fifteen of thirty-six cases of coronary occlusion. Boyd and Werblow<sup>2</sup> believe that painless coronary thrombosis must be fairly common, since one third of their 127 patients with proved coronary thrombosis did not manifest pain. A somewhat dissenting opinion is expressed by Kennedy,<sup>3</sup> who found in a recent study of 200 necropsies in cases of myocardial infarction that classic pain was present in 91 per cent of the recent and 64 per cent of the old cases. It appears from numerous observations that while the presence of actual occlusion of the coronary artery favored the occurrence of pain in about two thirds of the cases, the reverse is not true. There must therefore exist still another factor besides thrombosis on which the initiation of cardiac pain depends. Gorham and Martin's study suggests that painless coronary occlusion represents a more gradually developing pathologic process in which the progressive narrowing of the artery results from fibrosis rather than from actual thrombosis.

The cause of initiation of cardiac pain has been the subject of much speculation and in recent years of extensive experimental study. Allbutt's and Wenckebach's mechanical theory of the aortic origin of pain has been largely displaced by Lewis's conception of a chemical origin of pain originating in the heart muscle. His observations on pain produced in a limb which was exercised while its blood supply was arrested led him to believe that cardiac pain was dependent on the myocardial ischemia resulting from the impairment of the coronary circulation. This led to the development in the heart muscle of an unknown chemical "P substance" which acts as a pain producing stimulus to the nerve endings. Herrick explained the absence of pain in some cases in the presence of an extreme grade of ischemia by assuming that in such areas there existed a destruction of vessels, nerves and functioning muscle so that a painful response to the new obstruction was lacking. In recently reported experiments Martin and Gorham<sup>4</sup> attempt to prove that the mechanical factor of tension within the coronary arteries may be of major significance in the production of pain. These authors inquire as to why the receptors of pain sensations (afferent sympathetic fibers) in the coronary arteries, like pain receptors elsewhere in the body, may not be subject to mechanical as well as chemical stimulation. Following the technic and the criteria of Lueth and Sutton, they demonstrated that a typical pain response can be elicited in a dog when tridirectional tension is applied to a coronary vessel in such a manner as to cause no change in blood flow. With this procedure the chemical factors caused by impaired coronary blood flow are completely eliminated. The authors conclude that ten-

3. Kennedy, J. A.: The Incidence of Myocardial Infarction Without Pain in 200 Autopsied Cases, *Am. Heart J.* 14: 703 (Dec.) 1937.

4. Martin, S. J., and Gorham, L. W.: Cardiac Pain: An Experimental Study with Reference to the Tension Factor, *Arch. Int. Med.* 62: 840 (Nov.) 1938.

sion alone on the coronary arteries in dogs may serve as an adequate stimulation for the initiation of cardiac pain.

Obviously all discussion of cardiac pain must, at least for the present, remain somewhat speculative, in view of the fact that the mechanisms of the production of pain are as yet but little understood.

### HERBAL TREATMENT OF DIABETES

Notwithstanding the tremendous publicity given to the modern scientific treatment of diabetes, reports continue to appear of deaths following discontinuance of insulin by some patient on the recommendation of osteopaths, Christian science healers, naturopaths and herbalists. The London *Lancet* (Oct. 8, 1938, p. 849) recently noted such a case:

During an inquest last week it was alleged that a herbalist had dissuaded a diabetic patient from receiving insulin treatment. The deceased, a young man of 22, last year developed symptoms which were attributed to diabetes. A doctor prescribed insulin injections and four or five were given. Afterwards the young man's father, according to his own evidence at the inquest, decided that dietetic treatment would meet the case. Having been treated both by a registered medical practitioner and an osteopath, the patient went to Mr. T. H. Wilbraham of Ellesmere-road, Altrincham, a herbalist. The father told the coroner that Mr. Wilbraham said he specialized in the treatment of diabetics and strongly disapproved the use of insulin. The young man's condition, said his father, improved until the beginning of last August. On Sept. 4th a doctor ordered his immediate removal to hospital. He was admitted to a Stockport hospital in a state of coma and died next day. Dr. W. H. Grace, who gave evidence on the pathological side of the case, attributed the coma to the exclusion of insulin. On behalf of Mr. Wilbraham the father was asked in cross-examination whether Mr. Wilbraham had not suggested that, during his treatment, a doctor should administer the correct insulin injections. This the father denied. The coroner's jury returned a verdict of manslaughter, and Mr. Wilbraham was committed for trial.

Not long ago an article advocating a new herb for the oral, non-insulin treatment of diabetes mellitus appeared in the *Canadian Medical Association Journal* (July 1938, p. 32). Gobind Lal, Hearst science editor, among others, called attention to the article, and thus it was relayed to the general public. Several herbs are known to contain hypoglycemic principles. However, no one with the simplest understanding of the physiology of the pancreas and pathology of diabetes mellitus would ever consider any of them as adequate substitutes for insulin. Incidentally, the article in the Canadian journal referred only to some preliminary experiments on animals and observation of the effects in one human case.

Innumerable investigators continue to seek an oral preparation which will suitably control diabetes. The experiments thus far have not given much promise of success. In the meantime, therefore, physicians may well emphasize constantly the specificity of insulin in the successful management of diabetes. Successful management of the disease with insulin means prolongation of life. Until some preparation equal or superior to insulin is developed, patients must be made to

realize the dangers of using any other remedy, particularly any herbal preparation which may be advocated, usually on the basis of avoiding hypodermic injections. Many such preparations have come to the attention of the various Bureaus and Councils of the American Medical Association. The Council on Pharmacy and Chemistry has declared some of them unacceptable,<sup>1</sup> and the Bureau of Investigation has reported an extensive list of unsuccessful remedies for this condition.<sup>2</sup> Premature publication of experimental results may menace the lives of human beings. When such items are exploited by the press, people are led to abandon specific treatment which to them may mean the difference between life and death. While all may earnestly hope for the day when a successful oral treatment of diabetes will become available, today we must exert every effort to educate the victims of this disease in the dangers of abandoning life-saving insulin preparations.

### DESTRUCTION OF VITAMIN C IN THE GASTROINTESTINAL TRACT

Sufficient gastrointestinal fermentation of vitamin C may take place in certain persons to cause vitamin deficiency. In connection with this assertion Kendall and Chinn<sup>1</sup> of Northwestern University Medical School suggest a plausible method for the dietary control of this excessive fermentation. The effect of gastrointestinal bacteria on vitamin C (or on synthetic ascorbic acid) has been the subject of much experimental study during recent years. Stepp and Schröder,<sup>2</sup> for example, tested eight strains of *Bacillus coli* for their destructive action and found but one strain that would utilize ascorbic acid in vitro. Novotel'nov and Vodova<sup>3</sup> tested most of the known species of gastrointestinal bacteria and found none that would destroy vitamin C. The general conclusion<sup>4</sup> drawn from the accumulated evidence is that ability to use ascorbic acid is occasionally shown by certain individuals of known bacterial species but is not a common property of any known species. Kendall and Chinn, however, call attention to the

1. Since the time of its organization in 1905, the Council on Pharmacy and Chemistry has reported unfavorably on a number of proprietary medicinal articles which have been proposed for use in the treatment of diabetes. A list of these preparations follows: Cellasin, Filudine, Globeol, Succinolac, Hemo-Therapin, Chlorax, Intarvin, Diabesan, Blueberry Leaf Extract, Recresal, Sulfobetol, Eubetin, Tryptoferm, Pancresal Tablets, Imbak Preparations and Anticomane.

2. The Bureau has publicized hundreds of fake diabetes "cures" and "treatments." Dr. Arthur J. Cramp, in *Hygeia* for October 1935, discussed or mentioned the following: Amber-ita, Banbar, Bauer's Antibioticum, Beto, Marie Carr Fraud, Diabesan, Dia-Bet, Diabeticine, Diabetol, Diabetylin, Diaplex, Dill's Diabetic Mixture, Eksip, Expurgo (Sanol) Anti-Diabetes, Flowering Herb, Insoloid, Jamun Compound, Kaadt Treatment, Kelpe'koe, Korectone, Letone, Lifcore, Melatol, Mel-Tex, Pancretone, Photo-Synthetic Tea, Sal-Sano, Sanborn Treatment, Scheidemann's Shrub Remedy, Uvursin, Vinculin, Vindor Diabetic Wine, Warner's Safe Diabetes Remedy and Winroy. Since the appearance of that article, the Bureau of Investigation has published reports on the following related subjects which are not mentioned in the article: Linden Ray Emerick, M.D., Carr Laboratories, Sanovapor Dexene, Special Treatment for Diabetes [sic], Diatone and Delatol Laboratories.

1. Kendall, Arthur Isaac, and Chinn, Herman: *J. Infect. Dis.* **62**: 330 (May-June) 1938.

2. Stepp, W., and Schröder, H.: *Klin. Wchnschr.* **14**: 147 (Feb. 2) 1935.

3. Novotel'nov, N. V., and Vodova, V. A.: *Proc. Sci. Inst. Vitamin Research U. S. S. R.* **2**: 81 (No. 1) 1937; abstr., *Chem. Abstr.* **31**: 8615 (Nov. 20) 1937.

4. von Gagy, J.: *Klin. Wchnschr.* **15**: 190 (Feb. 8) 1936. von Gagy, J., and Ujsághy, P., *ibid.* **15**: 793 (May 30) 1936.

fact that routine plating methods used by previous investigators are not well designed to show the real frequency of vitaminolytic variants; so they devised an enrichment method, an ascorbic acid broth in which vitamin C fermenters tend to overgrow nonfermenting variants. After twenty-four hours' growth in this differential medium, ordinary plating methods are used.

The Chicago bacteriologists applied this differential technic to a bacteriologic study of stomach contents from patients with pernicious anemia and from patients with achlorhydria, to feces from babies and adults and to the intestinal contents of guinea pigs. Thirty-four ascorbic acid fermenting strains were isolated, almost every sample tested yielding positive results. Twenty-two of these vitaminolytic strains were classified as *Mucosus capsulatus*. Within twelve hours a strongly lytic strain may destroy approximately 50 per cent of the vitamin C present in their routine ascorbic acid broth and fully 97.5 per cent by the end of twenty hours. This destruction occurs under both aerobic and anaerobic conditions.

The Northwestern University bacteriologists found that the presence of even small amounts of dextrose (and by inference other simple, readily fermentable sugars) definitely postpones decomposition of ascorbic acid until all the dextrose is hydrolyzed. Since citrus fruits are rich in simple sugars, it would seem probable that these sugars will deflect microbic attack on vitamin C as long as the sugars are present in the digestive tract. Whether or not cane sugar added to fruit will further inhibit vitamin destruction was not tested.

## Current Comment

### TUBERCULOSIS IN YOUNG WOMEN

Why should tuberculosis be taking a relatively heavier toll from young women than from any other group of the population? Information on this question was obtained by the National Tuberculosis Association<sup>1</sup> through investigation of the homes of all girls and women between 15 and 25 who died from tuberculosis in New York City in 1929 and of a similar group who died in Detroit during 1930. In New York City the number investigated was 678 and in Detroit 180. One of the most striking facts brought out by the study was the relative similarity of the main observations in the two cities in spite of the fact that the tuberculosis death rate among young women was only 83 per hundred thousand in New York City as compared with 138 per hundred thousand in Detroit. The investigation allowed several specific conclusions, among which were that both cities have an appreciable Negro problem, tuberculosis takes the highest toll in late adolescence and early adult life rather than school age, and race, nativity, residence and immigration seem to have no essential relation to the problem, although the variations in racial susceptibility noted in other groups was

also evident here. There was no evidence of greater mortality among uneducated than among educated girls. There was no reason to believe that industrialization or any specific occupation was responsible for the unequal ratio between the tuberculosis death rates of this group and others or that increased tuberculosis mortality among young women is due to insufficient clothing, diet, lack of sleep or unusual recreational habits. Although it could not be statistically proved, it is believed that the psychic and physical changes of adolescence and early adult life cause young women to be unusually susceptible to tuberculosis and constitute the fundamental reasons for the high mortality rates which they sustain. A distinct relationship between pregnancy and the onset of tuberculosis was shown. Finally, the report concluded that the symptoms of tuberculosis were often recognized late with consequent delay in securing medical advice and treatment, and that clinic facilities were not widely used or sanatorium care given sufficiently early or consistently. As a result of this study the author believes that the excess tuberculosis in young women is essentially biologic rather than environmental in origin.

### INCIDENCE OF MOTTLED ENAMEL AFTER CHANGE OF WATER SUPPLY

The presence of fluoride in drinking water is responsible for the occurrence of "mottled enamel." Fluoride affects the unerupted tooth rather than the fully developed tooth, thus accounting for the prevalence of the condition in restricted age groups even though all use the same source of drinking water. The incidence of mottled enamel in a locality prominent in the history of this dental condition, Bauxite, Ark., has recently been redetermined<sup>1</sup> ten years after a change in the common water supply from one containing significant amounts of fluoride to one free from this substance. At the time of the first Public Health Service survey in Bauxite, in 1928, 44 per cent of all school children between the ages of 5 and 18 years showed definite evidence of mottled enamel and sixty-one of sixty-three children of this age who were born in Bauxite and had always lived there were affected. The occurrence of dental fluorosis in children of this age group was attributed directly to the fact that the city water supply from 1909 to the date of the early survey was obtained from a deep well the water of which contained significant amounts of fluoride. In 1928 the use of the deep well was discontinued, filtered river water being employed instead. The fluoride content of the latter was found to be negligible. Early this year a new survey of the incidence of mottled enamel in Bauxite school children was made. A decrease in the occurrence of the condition to practically zero was found in those children whose teeth had erupted since the water supply had been changed. These observations are the second recorded successful instance in the United States in which it has been shown that the changing of a water supply from one containing fluoride to one free from this substance can bring about a complete eradication of endemic mottled enamel.

# ORGANIZATION SECTION

## THE SPECIAL GRAND JURY RETURNS INDICTMENTS

The Special Federal Grand Jury, which has been conducting an investigation in Washington, D. C., for more than two months, returned indictments, December 20, charging violation of the Anti-Trust Laws against the American Medical Association, the Medical Society of the District of Columbia, the Harris County (Texas) Medical Society, the Washington (D. C.) Academy of Surgery, and twenty-one individuals. The specific test of applicability of the anti-trust statutes to the medical profession was based on the District of Columbia cooperative, known as Group Health Association, Inc. The indictment charged the defendants with conspiring to "hinder and obstruct Group Health Association, Inc., in obtaining access to hospital facilities for its members." The indictment was signed by Thurman Arnold, Assistant Attorney General of the United States, David A. Pine, United States Attorney for the District of Columbia, and John Henry Lewin, Allan Hart, Douglas B. Maggs and Grant W. Kelleher, special assistants to the Attorney General. According to United Press reports, the indictment charged the defendants with "having combined and conspired together for the purpose of restraining trade in the District of Columbia"; that is to say: "(1) for the purpose of restraining Group Health Association, Inc., in its business of arranging for the provision of medical care and hospitalization to its members and their dependents on a risk-sharing prepayment basis, (2) for the purpose of restraining the members of Group Health Association, Inc. [in Washington], in obtaining, by cooperative efforts, adequate medical care for themselves and their dependents from doctors engaged in group medical practice on a risk-sharing prepayment basis, (3) for the purpose of restraining the doctors serving on the medical staff of said Group Health Association, Inc., in the pursuit of their calling, (4) for the purpose of restraining doctors (not on the medical staff of Group

Health Association, Inc.) practicing in the District of Columbia, including the doctors so practicing who are made defendants herein, in the pursuit of their callings, (5) for the purpose of restraining the Washington hospitals in the business of operating such hospitals.

"In so doing, defendants have then and there engaged in an unlawful combination and conspiracy in restraint of trade in and of the District of Columbia, in violation of Section III of the Act of Congress on June 2, 1890, known as the Sherman Anti-Trust Act."

"Plans, understandings and agreements to accomplish the unlawful business herein above described were proposed, discussed and adopted at such meetings" (the indictment apparently refers here to meetings of the Medical Society of the District of Columbia, at which the Group Health Association, Inc., was discussed).

In announcing the decision of the government to press for criminal indictments, Mr. Arnold is reported to have said that such procedures seemed the only method to resolve the issues raised in the situation. The individuals indicted include Dr. Olin West, secretary and general manager of the American Medical Association, Dr. Morris Fishbein, editor of THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, Dr. Rosco G. Leland, director of the Bureau of Medical Economics, Dr. William C. Woodward, director of the Bureau of Legal Medicine and Legislation, and Dr. William D. Cutter, secretary of the Council on Medical Education and Hospitals, all from the headquarters of the Association in Chicago. The following remaining individuals named in the indictments are all from the District of Columbia: Drs. Arthur C. Christie, Coursen B. Conklin, James Bayard Gregg Custis, Thomas A. Groover, Robert A. Hooe, Leon A. Martel, Thomas E. Mattingly, Francis X. McGovern, Thomas E. Neill, Edward H. Reede, William M. Sprigg, William J. Stanton, John O. Warfield Jr., Prentiss Willson, Wallace M. Yater and Joseph R. Young.

## THE PACIFIC COAST ECONOMIC CONFERENCE

The second Pacific Coast conference was held at Portland, Ore., December 4. The meeting was attended by representatives from California, Idaho, Oregon and Washington.

Organized medicine now finds itself faced with so many problems and so much to consider that every possible method of reaching solutions must be utilized. With expectation that the Pacific states might help one another in solution of similar problems, the first Pacific Coast conference was called in San Francisco last February. Those in attendance were impressed with the unity of needs of organized medicine in the Pacific region and therefore anticipated an even more valuable conference when Charles Sears, president of the Oregon State Medical Society, invited representatives from Arizona, California, Idaho, Nevada and Washington to meet with the Oregon group in Portland.

Such similarity of problems and so many matters of regional interest were brought to light, and so much information was given on activities of neighboring state organizations, that the conference was established as a permanent organization. Henceforth it is to be known as the Pacific States Medical Executives' Conference and will draw its personnel from those in positions

of responsibility in state associations of California, Idaho, Montana, Nevada, Oregon, Utah, Washington and Wyoming. The next meeting is scheduled for Seattle.

The conference is not to be a legislative body but is intended only to be mutually advisory and a means of trading ideas for solution of problems confronting state organizations of the Pacific region.

The most interesting feature of the Portland meeting was the discussion by members of the California delegation of plans to be brought before a special meeting of the California house of delegates, December 17. Owing to the importance of the proposals revealed and the fact that they had not yet been officially acted on, the California participants requested that their discussion remain unreported. Official report of the coming meeting of the California house of delegates will reveal the extensive nature of the far-reaching plans proposed for California. Those in attendance at the Portland conference appreciated the opportunity of this preview afforded by the California delegation, and the many questions brought out were evidence of the interest evoked. Next in interest was the discussion of several federal activities in regard to medical care. The first discussion on

these matters came from V. W. Spickard, Seattle, who warned of the attempts of welfare and social departments to obtain administrative authority over funds now appropriated and probably to be appropriated by the federal government in the coming legislative session. It was his thought that such funds, appropriated for furthering health activities, should be administered as far as possible through state boards of health or state health departments. It was suggested that the advantages of such power might be misused by such departments of health as were not in close contact with the aims and purposes of organized medicine. This objection, however, was answered when it was brought out that as a general principle state departments of health are usually more closely attuned to the ideals of organized medicine than are departments of social welfare. All representatives at the conference saw the importance of this suggestion, and a resolution was passed to the effect that each state organization make vigorous effort to have federal funds for health activities controlled by state departments of health rather than by departments of welfare.

As a portion of the discussion on federal funds, the proposals of the federal farm security plans for medical care were discussed. The consensus was that it is possible to handle this type of work only through county and local societies. Since it has been extremely difficult to get the federal administrator to accept any responsibility for statewide plans, it was brought out that the local societies should be cautioned against accepting fee schedules too small to provide adequate service. Fear was expressed that acceptance by one county society of very small fees might be used to influence other societies toward impractical contracts.

The afternoon session of the conference brought out a discussion of methods of publicizing organization policies and activities to both the medical profession and the lay public. The meeting was closed after discussion by Martzloff of Oregon and Dudley of Washington on malpractice insurance. Oregon's

plan of granting monopoly to one insurance carrier was explained in some detail by Martzloff. He stated that cost of insurance to members of the Oregon State Medical Society had by this plan been reduced to unbelievably low figures, suits had markedly diminished in number, and splendid cooperation had been obtained between the insurer and the society. Dudley explained the workings of the Washington state medical defense fund. Those in attendance at the meeting were Charles Sears, president of the Oregon State Medical Society, chairman of the conference; John Fitzgibbon, Portland, Ore., delegate to the American Medical Association; Morris Bridgeman, Portland, secretary, Oregon State Medical Society; Mr. Clyde Foley, executive secretary, Oregon State Medical Society and secretary of the conference; Charles Manlove, hospital executive of Portland; Charles Hunt, Eugene, president-elect, Oregon State Medical Society; Karl Martzloff, Portland, member of the council of the Oregon State Medical Society. Other members of the Council of the Oregon State Medical Society were Leslie Kent, Eugene; Frank Power, Salem, and George Henton, Portland. Ralph A. Fenton, Portland, trustee of the American Medical Association, was also present. Washington was represented by Harry Rhodhamel, Spokane, president of the Washington State Medical Association; V. W. Spickard, Seattle, secretary of the Washington State Medical Association; Mr. Jack Geoffroy, executive secretary, Washington State Medical Association; Ray Zech, Seattle, delegate to the American Medical Association; C. W. Knudson, president, King County Medical Society and Washington Public Health League; H. D. Dudley, Seattle, director of the Medical Defense Fund, and H. L. Hartley, Seattle, assistant editor, *Northwest Medicine*. Idaho was represented by Frank Gibson, Potlatch, president, Idaho State Medical Association, and J. N. Davis, Twin Falls, secretary. The California delegation consisted of George Kress, San Francisco, secretary of the California Medical Association and editor of *California and Western Medicine*; George Reinle, Oakland, and Charles Dukes, Oakland.

## OFFICIAL NOTES

### WITNESSES BEFORE THE SPECIAL GRAND JURY IN WASHINGTON

The following witnesses are reported to have appeared before the Special Grand Jury in Washington: Dr. William W. Bauer, Chicago, director of the Bureau of Health Education, who presented the documents which had been subpoenaed from the American Medical Association headquarters; Mr. Theodore Wiprud, secretary of the Medical Society of the District of Columbia, who presented further documents to the jury, and Dr. Francis X. McGovern, chairman of the executive committee of the Medical Society of the District of Columbia.

### RADIO BROADCASTS

The fourth series of programs broadcast in dramatic form portraying fictitious but typical incidents of significance in relation to health by the American Medical Association and the National Broadcasting Company, entitled "Your Health," began Wednesday October 19 and will run consecutively for thirty-six weeks. The program is broadcast each Wednesday over the Blue network of the National Broadcasting Company at 2 p. m. eastern standard time (1 p. m. central standard time, 12 noon mountain time, 11 a. m. Pacific time).<sup>1</sup>

These programs are broadcast on what is known in radio as a sustaining basis; that is, the time is furnished gratis by the radio network and local stations and no revenue is derived from the programs. Therefore, local stations may or may not take the program, at their discretion, except those stations which are owned and operated by the National Broadcasting Company.

The next three programs to be broadcast, together with their dates and their topics, are as follows:

December 28.	Good Milk. Good for You.
January 4.	Fool's Gold.
January 11.	Only a Cold!

### THE ST. LOUIS SESSION

#### Application for Space in the Scientific Exhibit Must Be Made by January 5

Attention is drawn to the fact that applications for space in the Scientific Exhibit at the St. Louis Session will close on January 5. Application blanks will be sent on request to the Director, Scientific Exhibit, American Medical Association, 535 North Dearborn Street, Chicago.

### CALIFORNIA APPROVES PLAN FOR MEDICAL CARE

At a special meeting of the house of delegates of the California Medical Association in Los Angeles December 17 a plan to provide medical care to residents of the state at a cost of about \$2.50 a month was approved. According to the *New York Times*, patients will select their own doctors and hospitals. Payments will be made on a weekly, monthly or semimonthly basis. Physicians will be paid on a unit basis, the payments graded from single units for minor services to twenty-five or more units for major operations. It is expected to take about six or eight months to put the plan into operation. While the exact cost has not been determined, the estimate is \$2.50 a month for each person. No provision for family group insurance was made under the revised final plan. Hospital, medical and surgical attention will be provided and the expense may be lower if 500,000 or more persons participate in the plan.

1. Owing to program conflicts, there will be no Chicago broadcast of the network program. Instead, a recording of the program will be broadcast over station WENR at 8 p. m. each Wednesday. This recording will be an identical rebroadcast of the network program broadcast earlier the same day.

## Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

ADDITIONAL MEDICAL COLLEGE NEWS AND ARTICLES APPEAR IN THE STUDENT SECTION, PAGE 2444.

### CALIFORNIA

**Changes in Health Officers.**—Dr. William A. Clarke has been appointed health officer of Holtville to succeed Dr. Harry B. Graeser. The city of San Mateo has contracted with the county of San Mateo to administer its public health under the county health unit, of which Dr. Charles C. Gans, Redwood City, is health officer. Dr. James A. Warburton has served for many years as health officer of the city.

**Annual Surgical Meeting.**—The Los Angeles Surgical Society held its annual meeting at the Los Angeles County General Hospital and the Los Angeles County Medical Association Building December 9-10. In addition to clinics the following papers were presented among others:

- Dr. John W. Budd Jr., Intraductal Papilloma and Carcinoma of the Breast.
- Dr. Rafe C. Chaffin, Surgical Drainage, Special Application of the Suction Principle.
- Dr. Alvin G. Foord, Physiologic Changes in the Leukocyte Count.
- Dr. Edward C. Pallette, Liver Abscess with Perforation.
- Dr. Harold L. Thompson, Mortality of Acute Perforation of Peptic Ulcer.
- Drs. George H. Houck and Frank S. Dolley, Amebiasis with Liver Abscess and Spontaneous Bronchial Drainage.

### CONNECTICUT

**Study of the Human Element in Motor Accidents.**—A comprehensive study of the human element in motor vehicle accidents will be made at the Institute of Human Relations of Yale University, New Haven, according to the *New York Times*. Cooperating will be the American Association of Motor Vehicle Administration, which instigated the project, and the Standard Oil Company of New Jersey, which is providing the funds. The association of motor vehicle administrators is composed of state officials who are directly concerned with the regulation of motor vehicles. The state motor vehicle commissioners will give the use of their departments so that research work can be carried on in various states. Complete reports will be made available to the project and the administrators will also furnish assistants to cooperate in individual studies. The association has also appointed a committee to cooperate in the project. The Standard Oil Company will make available its driver records and its safety and motor vehicle operating information.

### IDAHO

**Hospital News.**—A county hospital for Oneida County was recently dedicated at Malad.—PWA funds have been granted for a hospital in Lewis County at Nez Perce. The grant was \$8,100, and 55 per cent of the cost of the hospital will come from a bequest from Charles E. Burkhart.—A general hospital is to be built at Grangeville with a PWA grant of \$17,286 and \$22,000 collected and pledged by the city.

**Society News.**—Dr. Samuel M. Poindexter, Boise, discussed coronary disease before the Pocatello Medical Society in Pocatello November 23. At this meeting members of the former Upper Snake River Medical Society, including the territory from Rexburg to Ashton, asked for permission to withdraw from the Pocatello society in order to reorganize in their own territory.—Drs. Joseph Melvin Asprey and Norman R. Brown, Spokane, Wash., addressed the North Idaho Medical Society, Lewiston, October 19 on "Newer Developments in the Treatment of Cancer" and "Certain Problems of Treatment of Fractures" respectively. A film on "Typing of Pneumococci and Serum Treatment of Pneumonia" was shown.

### ILLINOIS

**Dedication of New Buildings at State Hospital.**—New buildings at Anna State Hospital, erected during the past five years at a cost of \$1,275,121, were dedicated October 15. Mr. A. L. Bowen, director of the state department of public welfare, gave the dedicatory address. The recreation hall in which the ceremonies took place was named in honor of the late Dr. Ralph A. Goodner; other buildings have been named

for Drs. W. C. Lence and William L. Athon, former managing officers of the institution. A portrait of Dr. Goodner was unveiled. Funds for remodeling and new buildings were supplied through state appropriation and PWA grants. The Athon and Lence cottages are of the one story "E-type" construction which is standard for state mental hospitals and contain 120 beds each. A 132 bed diagnostic center and hospital is now nearing completion.

### CHICAGO

**Society News.**—The Chicago Society of Internal Medicine was addressed December 19, among others, by Dr. Louis R. Limarzi and Emil M. Schleicher on "The Reaction of Peripheral Blood and Bone Marrow in Chronic Hemorrhage and in Essential Thrombocytopenic Purpura," and Dr. Carl C. Pfeiffer, "Effect of Analeptic Drugs in Hibernating Ground Squirrels."—Dr. Mabel E. Gardner, Cincinnati, addressed a joint meeting of the Chicago Council of Medical Women and the American Medical Women's Association November 9 on "Medical Women versus War."—At a meeting of the Chicago Roentgen Society November 10 Dr. Paul H. Holinger, among others, discussed "Biplane Fluoroscopy as an Adjunct to Bronchoscopy."—The Chicago Pediatric Society was addressed November 10 by Drs. Harold C. Stuart, Boston, and Mandel Sherman on "The Observation of Growth in Pediatric Practice: Useful Research Contributions" and "Classification and Interpretation of Neurotic and Abnormal Behavior of Children" respectively.—At a meeting of the Chicago Pathological Society November 14 Drs. George J. Rukstinat and Robert J. Hasterlik, among others, spoke on "Congenital Absence of the Penis."

### KANSAS

**Causes of Death in Kansas.**—There were 19,287 deaths recorded in Kansas during 1937. Of this total, 13,797 deaths, or 71 per cent, were the result of the ten leading causes, 7,924 in men and 5,873 in women, according to the *Medical Bulletin* of the Sedgwick County Medical Society. Heart disease continued to lead the causes of death with a total of 3,192 and following, in the order named, are the remainder comprising this group: cancer, accounting for 2,168; cerebral hemorrhage, 1,733; chronic nephritis, 1,590; "all accidents," 1,492; pneumonia, 1,126; diseases of the coronary arteries, 792; influenza (all forms), 686; motor vehicle accidents, 520, and tuberculosis, 498.

**Society News.**—Dr. Sumner L. S. Koch, Chicago, addressed the Shawnee County Medical Society in Topeka, October 3, on "Surgical Principles in Care of Injuries and Infections of the Hand."—At a meeting of the Bourbon County Medical Society in Fort Scott, October 24, Drs. Caryl R. Ferris and Claude J. Hunt, Kansas City, Mo., discussed "Advances Made in the Treatment of Diabetes" and "Problems in Thyroid Diseases," respectively.—The Marion County Medical Society was addressed in Marion October 25 together with the McPherson and Harvey county medical societies. Dr. Christian A. Hellwig, Wichita, spoke on "Analysis of Causes of Uterine Bleeding After the Age of 40 Years" and Philip W. Morgan, Emporia, "Electrocardiography and the Evaluation of Heart Symptoms."—Dr. Thomas L. Foster, Larned, discussed "New Treatments of Insanity" before the Pawnee County Medical Society in Larned recently.

### KENTUCKY

**District Meeting.**—The Sixth and Seventh Councilor Districts of the Kentucky State Medical Association held a joint meeting in Somerset November 4. The speakers included Drs. Harry S. Andrews, Louisville, "Management of Premature Infants"; Nevil M. Garrett, Brodhead, "Immediate Repair of Perineal Lacerations," and John W. Scott, Lexington, "Common Diseases of the Liver and Gallbladder."

### MARYLAND

**Expansion of Tuberculosis Activities.**—With funds made available by the Maryland Tuberculosis Association, Dr. Raymond Hussey, Baltimore, has been appointed field medical investigator for applicants for admission in state sanatoriums from Baltimore. Provision has been made also for two public health nurses. The board of managers of the state tuberculosis sanatorium commission has felt the need of an improved method of admitting patients. Heretofore applications have been sent directly to the superintendents of the various institutions and admissions were made in the order in which the applications were received. This has not proved

entirely satisfactory. Under the new plan Dr. Hussey will receive all applications from persons living in Baltimore and investigate each case with particular reference to the suitability of the patient for sanatorium care and the need for isolation. Dr. Hussey will visit the patient with or without the family physician and will take the necessary steps for admission without charge to the patient. Buildings now under construction for 200 additional patients will be ready for occupancy Oct. 1, 1939. In addition, the board of managers plans to request the next legislature for funds to provide for an extra 100 beds at Henryton, the sanatorium for colored persons, and to establish a branch hospital for colored patients on the Eastern shore.

### MASSACHUSETTS

**Departments of Tropical Medicine and Comparative Pathology Merged.**—The department of tropical medicine, Harvard University Medical School, Boston, and the department of comparative pathology have been consolidated. The change was effected on the retirement of Dr. Richard P. Strong early this fall as professor of tropical medicine. The combined department is now under the supervision of Dr. Ernest E. Tyzzer, George Fabyan professor of comparative pathology.

**Society News.**—At a meeting of the Boston Society of Psychiatry and Neurology October 20 the speakers were Drs. Arthur L. Watkins on "The Cerebrospinal Fluid in Retrobulbar Neuritis" and Michael S. Burman, New York, "Observations on Spastic Paralysis and Dystonia Musculorum Deformans."—Dr. William H. Watters, Boston, addressed the New England Society of Physical Medicine October 19 on "Physical Medicine in Chronic Disease."—At a meeting of the Harvard Medical Society in Boston October 25 Dr. Henry A. Christian, Boston, spoke on "Certain Cardio-renal Circulatory Correlations."—Dr. George E. Hall, Toronto, discussed "Neurogenic Influences in Experimental Coronary Artery Disease" before the New England Heart Association in Boston October 26.

**Director of New Department of Mental Health.**—Dr. Clifton T. Perkins, acting commissioner, state department of mental diseases, has been appointed commissioner of the new state department of mental health and Dr. Bardwell H. Flower, assistant superintendent of the Grafton State Hospital, was appointed assistant commissioner. The department is the outgrowth of a recent reorganization of the state department of mental diseases, of which Dr. David L. Williams was the former commissioner. The law authorizing the change was enacted July 7. Dr. Perkins graduated at the Boston University School of Medicine in 1926. Subsequently he served on the staff of the Worcester State Hospital, as assistant to the commissioner of mental diseases, assistant commissioner and acting commissioner, and as a member of the faculty in the department of psychiatry in his alma mater.

### MICHIGAN

**Society News.**—Dr. Leo G. Rigler, Minneapolis, addressed the Calhoun County Medical Society in Battle Creek November 1 on "X-Ray Diagnosis of Acute Abdominal Conditions."—A symposium on the serum treatment of pneumonia was presented before the Washtenaw County Medical Society, Ann Arbor, November 8, by Drs. Abbott B. Mitchell, Lansing, Cyrus C. Sturgis, Herman H. Riecker and Dorman E. Lichty, Ann Arbor.—Dr. Frank A. Kelly, Detroit, discussed "Injection Treatment of Hernia" before the Genesee County Medical Society in Flint November 2. Dr. Douglas Donald, Detroit, discussed "Pitfalls in Diagnosis of Coronary Thrombosis" before this society in Flint November 16.—Dr. Frederick H. Falls, Chicago, addressed the Kalamazoo Academy of Medicine November 15 on "Early Recognition and Treatment of Cancer of the Cervix and Uterus."

**Home for Convalescent Girls.**—A home for convalescent girls in Detroit, the first in the state, has been established by Dr. B. Raymond Hoobler, emeritus professor of pediatrics, Wayne University College of Medicine, as a memorial to his wife, the late Madge Sibley Hoobler. Organized as a non-profit corporation, the Hoobler Guest House, with accommodations for twenty-five persons, was dedicated November 27. If the girl is under the care of a physician, she obtains his permission to go to the guest house. All admissions are made through Alice M. Walker, head of social service at Harper Hospital. When admitted, a girl may spend as much as two weeks without cost in an atmosphere of quiet refinement and healthful living. The guest house is the outcome

of a wish expressed by the late Mrs. Hoobler, who intended to dedicate it to her mother. According to the *Detroit Free Press*, Dr. Hoobler plans to make the present house the first of several in Detroit.

### MINNESOTA

**Program of Health Education.**—A coordinated program of health education, working through a committee representing interested agencies, is under way in Minnesota. A special topic will be chosen each month for discussion by hospital staffs and local societies, while the state medical society and the state board of health will send out bulletin information. The motion pictures, radio and weekly news services of the state society and other public health agencies will be utilized in disseminating information to the public. A tentative list of topics has been announced: January, pneumonia; February, pediatrics; March, degenerative and circulatory diseases; April, cancer; May, obstetrics and gynecology; September, traumatic surgery; October, syphilis and gonorrhea; November, tuberculosis and respiratory diseases, and December, anemias and deficiency diseases.

### MISSOURI

**Hospital News.**—Construction on a new state trachoma hospital on a three acre site adjoining the city of Rolla started November 29. Citizens of Rolla donated the property, and the \$75,000 appropriated by the state legislature will be supplemented by a federal grant of \$63,000.

**Society News.**—The Jackson County Medical Society has revised its charter and by-laws, effective January 1. The first election to be held under the new laws, however, will be held in 1940.—The Wyandotte County Medical Society was addressed in Kansas City November 15 by Dr. William Walter Wasson, Denver, on "The Anatomy, Physiology and Mechanics of the Chest as the Basis for Study and Classification of Diseases of the Chest."

### NEBRASKA

**District Meetings.**—At the annual meeting of the Seventh Councilor District Medical Society in Superior October 20 the speakers were Drs. Robert J. Stearns, Omaha, diseases of the cervix, exclusive of those secondary to birth injuries; Harold S. Morgan, Lincoln, "Etiology and Symptomatology of Injuries of the Birth Canal Due to Birth Injuries," and Maurice E. Grier, "Treatment of Injuries of the Birth Canal Due to Birth Injuries."—The Sixth Councilor District of the Nebraska State Medical Association met in Wahoo November 14 with the following speakers: Drs. Arthur L. Miller, Kimball, president-elect of the state association, on "Medicine of Tomorrow"; Herman F. Johnson, Omaha, "Treatment of Fractures of the Upper Extremities," and James E. M. Thomson, Lincoln, who presented a motion picture on "Fractures of the Spine."

### NEW JERSEY

**Personal.**—Dr. Earl S. Hallinger, Camden, was elected secretary of the State Board of Medical Examiners November 16 to succeed the late Dr. James J. McGuire.

**Thirty-Four Aliens Pass State Examinations.**—Thirty-four physicians who are refugees from various European countries passed a recent examination for licenses to practice in New Jersey, it is reported. They received six year licenses, which will continue in force if they become citizens within the period; otherwise the licenses will be automatically annulled. Twelve refugee candidates failed, according to the report. Forty-five of a class of fifty-eight citizens passed the examination.

**Society News.**—Dr. William Seaman Bainbridge, New York, addressed the Camden County Medical Society, Camden, December 6 on "The Cancer Problem of Today," with Dr. William Wayne Babcock, Philadelphia, as commentator.—Dr. Oswald S. Lowsley, New York, addressed the Academy of Medicine of Northern New Jersey, Newark, December 15, on "Some New Operative Procedures in Urology."—Col. Jay W. Grissinger, surgeon, Second Corps Area, U. S. Army, and Capt. Charles M. Oman, senior medical officer, Third Naval District, U. S. Navy, addressed the Essex County Medical Society, Newark, December 8, on "The Medical Profession in Relation to Military Preparedness."—Drs. John B. Flick, Philadelphia, and Berthold S. Pollak, Secaucus, addressed the Atlantic County Medical Society, Atlantic City, December 9, on surgical and medical treatment, respectively, of pulmonary tuberculosis.—Dr. Byron P. Stookey, New

York, addressed the Bergen County Medical Society, Hackensack December 13 on "Recent Developments in the Diagnosis and Treatment of Low Back Pains and Sciatica with Special Reference to Herniations of the Nucleus Pulposus."—Dr. Harvey F. Doe, Montclair, discussed the state program on pneumonia at a meeting of the Hudson County Medical Society, Jersey City, November 1. A film on serum treatment was shown.

## NEW YORK

**Obstetric Institute in Syracuse.**—An obstetric institute sponsored by the maternal welfare committee of the Onondaga County Medical Society was presented at the Syracuse University College of Medicine December 8. Among the subjects discussed were the use of sulfanilamide, use and interpretation of the Friedman test, home delivery technic, anesthesia and danger signals during labor. At a luncheon meeting Dr. Herman G. Weiskotten, dean of the medical school, spoke on opportunities for graduate studies in obstetrics.

## New York City

**Examinations for Physicians.**—The Municipal Civil Service Commission announces an examination to be held for physicians in the department of correction. There are four vacancies for women in the House of Detention and six for men at Rikers Island. The salary ranges from \$1,360 to \$1,800 a year. Full time service is required, with maintenance in certain cases. Candidates must be graduates of reputable medical schools and must have one year's experience as intern in a hospital of recognized standing or equivalent medical experience. They must be licensed to practice in New York before certification. Applications will be received up to Wednesday December 28.

**Medical Equipment for World's Fair.**—An automobile x-ray unit has been built for the medical division of the New York World's Fair. With the mobile unit the eight first aid stations will be provided with immediate x-ray service, especially in cases of suspected fractures or other internal injuries. Plates will be developed in the darkroom in the automobile, which is equipped with a dry ice device to keep the developer chemicals at the maximum level of efficiency. A special ambulance is being prepared for the work of the "division of pneumatology," which will have charge of administering gases at first aid stations and at two resuscitation centers. The ambulance will be fitted with modern equipment for care of all kinds of asphyxial accidents, such as asphyxiation from gas, submersion and fire fighting.

**Society News.**—Dr. Malcolm Goodridge was elected president of the New York Academy of Medicine for a two year term, succeeding Dr. James Alexander Miller. Dr. Rufus I. Cole, Mount Kisco, was elected vice president for three years and Dr. Bernard Sachs was made treasurer for three years.—The Physicians' Square Club of Greater New York held its one hundred and fiftieth dinner December 14 at the Hotel Westover. Dr. A. Bern Hirsh, editor of *New York Medical Week*, was the guest speaker on "Fifty Years in Medicine and Masonry."—A symposium on endocrinology was presented at the first fall meeting of the International Spanish Speaking Association of Physicians November 30 by Drs. James R. Goodall, Montreal, Canada; William F. Rienhoff Jr., Baltimore, and Murray B. Gordon, New York.

**Gifts to Columbia.**—Columbia University has received \$403,792.59 in cash gifts for medical purposes within recent months. Among the most important are the following:

Rockefeller Foundation, \$111,750; of this \$100,000 is to be for research in neurology over a five year period, \$7,000 for research on constitutional aspects of disease, \$2,750 for studies on the common cold and \$2,000 for research in chemical embryology.

Carnegie Corporation of New York, \$64,460; of this \$50,000 is for endowment of the program for graduate medicine, \$8,260 for chemical research in the department of biologic chemistry and \$1,500 for research on deficiency diseases in certain animals.

John and Mary R. Markle Foundation, \$54,800; of this \$24,600 is for cancer research at the Institute of Cancer Research on biologic effects of radiation.

Josiah Macy Jr. Foundation, \$26,260 for various departments. An anonymous donor, \$20,000 for research at the Institute of Cancer Research.

William J. Matheson Foundation, \$2,400 for the Matheson Encephalitis Fund in the department of bacteriology.

Philip Morris and Company, \$2,000 for research in pharmacology.

**Hospital Council Formed.**—The Hospital Council of Greater New York was formed at a meeting of various agencies November 10. It supersedes the Hospital Council of the City of New York formed in 1935, according to the *New York Times*. The council will be composed of seventeen organizations. They include the Coordinating Council of the Five County Medical Societies of New York City, New York

Academy of Medicine, United Hospital Fund, Merchants Association of New York and New York Board of Trade besides welfare, civic and religious groups and the city of New York. Its aim is to "improve and coordinate the services of hospitals and related health agencies" and to "plan the economical and efficient development of these services in relation to community needs." A planning committee of twenty-nine members will be in charge of the council's program.

## OHIO

**Postgraduate Day in Akron.**—Three Cincinnati physicians provided the program of the Summit County Medical Society's seventh annual Postgraduate Day November 16. Dr. Max M. Zininger spoke on "Surgical Lesions of the Stomach and Duodenum" and "Diagnosis and Surgical Treatment of Diseases of the Gallbladder and Bile Ducts"; Dr. Marion A. Blankenhorn, "Serum Treatment of Lobar Pneumonia" and "Bacterial Endocarditis"; John A. Caldwell, "Fractures of the Humerus" and "Fetish Worship in the Treatment of Fractures."

**District Meeting.**—The Ninth Council District of the Ohio State Medical Association held a meeting in Ironton November 16. Dr. Parke G. Smith, Cincinnati, president-elect of the state association, spoke on economic problems of the profession and Mr. Charles S. Nelson, Columbus, executive secretary, on organization matters. The scientific program was as follows: Drs. George W. Crile, Cleveland, on "Surgical Treatment of Hypertension"; Julian E. Benjamin, Cincinnati, "Functional Heart Tests," and Jonathan Forman, Columbus, "Allergy in Everyday Practice."

## OKLAHOMA

**Society News.**—At a meeting of the Carter County Medical Society in Ardmore October 17 the speakers were Drs. Leonard S. Willour, McAlester, on fractures; Glenn J. Collins, McAlester, the electrocardiograph as an aid in diagnosis, and Lyman C. Veazey, Ardmore, psychiatry in medicine.—Drs. Henry H. Turner and William M. Taylor, Oklahoma City, addressed a joint meeting of the Grady, Stephens and Caddo county medical societies recently at Anadarko on "Practical Endocrinology" and "Acute Respiratory Diseases of Childhood" respectively.—Drs. Carroll M. Pounders and George H. Garrison, Oklahoma City, addressed the Garfield County Medical Society, Enid, November 30, on "Juvenile Rheumatism" and "The Present Status of Poliomyelitis—Its Early Diagnosis and Treatment" respectively.

## OREGON

**Pacific Coast Medical Conference.**—The Oregon State Medical Society was host December 4 to a conference of state medical societies of the Far West in Portland. The Idaho, Nevada, Arizona, California and Washington associations were invited. Among topics discussed were methods of publicizing organization activities and policies, medical care of low wage groups, Farm Security Administration plans for medical care, industrial commission contracts with hospital associations and other corporations, the American Medical Association survey, graduate instruction, malpractice insurance, cooperation with other groups, legislative organization and technic.

## PENNSYLVANIA

**Graduate Assembly in Danville.**—The first graduate assembly of the year under the auspices of the Montour County Medical Society was held at Geisinger Hospital, Danville, November 18. The guests were Drs. Eugene F. Du Bois, New York, who spoke on "Temperature Regulation and Fever"; Charles C. Higgins, Cleveland, on "Renal Calculi—Etiology, Diagnosis and Treatment," and James H. Means, Boston, who conducted a clinic on heart disease. Dr. David W. Thomas, Lock Haven, president of the Medical Society of the State of Pennsylvania, spoke at a luncheon on "Postgraduate Seminars in Pennsylvania."

## Philadelphia

**Alumni Seminar for Pharmacists.**—The Philadelphia College of Pharmacy and Science has announced plans for a three day seminar for practicing pharmacists to give them a review of the latest developments in pharmacy, chemistry, bacteriology and biology. The dates are January 30 to February 1 during the midterm recess of the college. Subjects on the program for the lectures and demonstrations include dispensing of the new chemotherapeutic agents; demonstrations in physicochemical methods; endocrines, vitamins and hormones; the newer biologicals, and where to go for information on scientific prob-

lems. Any pharmacist, graduate of a recognized college of pharmacy, is eligible for enrolment. Full information may be obtained from John E. Kramer, B.Sc., registrar, Philadelphia College of Pharmacy and Science.

**Society News.**—Dr. Philip D. McMaster, New York, addressed the Pathological Society of Philadelphia November 10 on "Skin Lymphatic and Lymph Flow in Health and Disease" and Dr. Stanley P. Reimann and Mr. Barnard J. Miller, on "The Parthenogenic Extrusion of Polar Bodies from an Unfertilized Human Ovum."—At a meeting of the Northern Medical Association of Philadelphia November 21 the speakers were Drs. Leslie N. Gay, Baltimore, on "Complications of Bronchial Asthma and Their Treatment"; Aaron Brown, New York, "Pollen Desensitization and Its Complications," and Matthew S. Ersner, "Indications and Contraindications of Rhinologic Regimen and Surgical Intervention in Bronchial Asthma."—Dr. Edgar G. Ballenger, Atlanta, Ga., addressed the Philadelphia Urological Society November 28 on "Persistent Gonococcal and Other Infections."—Drs. Charles Mazer and George Baer, among others, addressed the Obstetrical Society of Philadelphia December 1 on "Therapeutic Value of Low-Dosage Irradiation of the Pituitary Gland and Ovaries in Functional Menstrual Disorders and Sterility."

### SOUTH CAROLINA

**Society News.**—South Carolina members of the South Atlantic Association of Obstetricians and Gynecologists held a meeting in Columbia November 5 with the committee on maternal welfare of the South Carolina Medical Association. Dr. Joseph Decherd Guess, Greenville, made an address on "The Problem of the Occiput Posterior Position" and Dr. John M. Fleming, Spartanburg, presented a paper on "Endometriosis of the Round Ligament." Motion pictures dealing with the investigation of sterility and with vaginal hysterectomy were shown.—Dr. Foster M. Routh, Columbia, addressed the Ridge Medical Society in Batesburg recently on allergy.—Dr. George H. Bunch, Columbia, discussed appendicitis at a meeting of the Coastal Medical Society in Walterboro October 27.

### TEXAS

**Society News.**—Dr. Charles T. Stone, Galveston, addressed the Bexar County Medical Society, San Antonio, October 6 on "The Physiologic Basis for the Treatment of Peptic Ulcer."—Drs. Sidney J. Wilson and Truman C. Terrell, Fort Worth, addressed the Tarrant County Medical Society, Fort Worth, October 4, on "Treatment of Mycosis Fungoides" and "A Comparative Study of Foille with Tannic Acid and Tannic Acid Preparations in the Treatment of Burns" respectively.—Drs. Carl Kaufman and Sam V. Granata, Beaumont, addressed the Jasper-Newton Counties Medical Society, Kirbyville, November 16, on asthma and allergy.—A symposium on fractures was presented before the Dallas County Medical Society November 10 by Drs. Charles F. Clayton, Fort Worth; James S. Speed, Memphis, Tenn., and Charles S. Venable, San Antonio.

### WEST VIRGINIA

**State Health Conference.**—Dr. Edwin Cameron, Morgantown, was elected president of the West Virginia Public Health Association at the annual conference in Bluefield October 31-November 2. Drs. Bruce H. Pollock, New Cumberland, and Claude A. Thomas, Martinsburg, were elected vice presidents. Among the speakers were Miss Katherine Lenroot, chief of the Children's Bureau, Washington, D. C.; Dr. Goldsborough Foard McGinnes, director of the bureau of communicable diseases, state department of health of Virginia, Richmond, and Dr. Mark V. Ziegler of the U. S. Public Health Service, Washington, D. C.

### WISCONSIN

**Dr. Sleyster Guest of Honor.**—The Medical Society of Milwaukee County and the Woman's Auxiliary held their annual dinner meeting December 8 at the Milwaukee Athletic Club with Dr. Rock Sleyster, Wauwatosa, President-Elect of the American Medical Association, guest of honor. Dr. Ernest E. Irons, clinical professor of medicine, Rush Medical College, Chicago, was the guest speaker and his subject "The Last Illness of Sir Joshua Reynolds."

**State Tuberculosis Meeting.**—The thirtieth annual meeting of the Wisconsin Antituberculosis Association was held in Milwaukee October 27-29. Dr. Frank J. Hirschboeck, Duluth, Minn., was the principal speaker at a medical meeting and clinic Thursday evening. The annual dinner was held Friday evening with Dr. Rock Sleyster, Wauwatosa, President-Elect

of the American Medical Association, as toastmaster. At a health education meeting Saturday the speakers were Dr. Paul A. Teschner, Chicago, assistant director, Bureau of Health Education, American Medical Association, on "Who Shall Teach?" and Dr. Amelia T. Wood, Muncie, Ind., "What Shall Be Taught?"

### GENERAL

**Social Hygiene Day.**—February 1 has been named as the date for the third observance of National Social Hygiene Day. An anonymous gift of \$15,000 for the \$500,000 fund sought by the National Anti-Syphilis Committee of the American Social Hygiene Association was recently announced. This brings the fund to \$187,065. The association has formulated an eight point program including plans to organize more local and state committees to fight gonorrhea and syphilis, encourage passage of laws for prevention of syphilis, fight prostitution and medical quackery, aid employers and employees against the economic losses caused by these diseases, extend information on social hygiene to the youth of America, expand the personal advisory and consultation service, guide parents, teachers and pastors in sound principles of sex education of youth, and continue observations and reports to citizens regarding official programs. "Guard Against Syphilis" has been chosen as the slogan for the 1939 observance of National Social Hygiene Day.

**New Prize for Vitamin Research.**—To promote interest in research on the water-soluble "B-complex" vitamins, Mead Johnson and Company, Evansville, Ind., has established an annual award of \$1,000 to be presented over a period of five years through the American Institute of Nutrition. A committee of members of the institute will select the recipient, and the presentation will be made a feature of its annual meeting each spring. The award will be given to the laboratory (nonclinical) or clinical research worker in the United States or Canada who in the opinion of the judges has published during the previous calendar year the most meritorious report dealing with the B-complex vitamins. If circumstances and justice dictate, the prize may be divided among two or more persons or it may be given to a worker for valuable contributions over an extended period, but not necessarily representative of a given year. Nominations may be sent at any time to Leonard A. Maynard, Ph.D., Laboratory of Animal Nutrition, Cornell University, Ithaca, N. Y. To be considered for the award at any given spring meeting, the nomination must be received by January 15.

**Medical Activities of the Red Cross.**—Important features of the activities of the American Red Cross during the past year, according to the annual report, were pellagra control, volunteer blood donor service, oral hygiene and venereal disease control. Red Cross public health nurses made 1,043,954 field visits, 214,398 of them on behalf of mothers and infants, during the fiscal year ended June 30. Each year the number of certificates issued for courses in home hygiene and care of the sick increases; the total number since the first awards in 1914 is 951,639. To prepare teachers for these courses, ninety-five institutes were held last year; nine colleges now give summer teacher training courses for this work. At the end of the third year of the highway emergency first aid program 2,454 stations had been established. Rigid inspection of these stations is maintained, the report says, and those not meeting the standards are withdrawn. Seventy-two agreements have been made with cooperating organizations designating 2,051 pieces of highway equipment as mobile first aid units. This was also the third year of the program of home and farm accident prevention. This activity has become an integral part of the Junior Red Cross program and has stimulated concern about accidents in school environments as well. Expenditures for the fiscal year amounted to \$10,358,566.21 and the resources as of July 1 to \$14,514,902.38. The year was marked by the death of Admiral Cary T. Grayson, the chairman, and appointment of Mr. Norman H. Davis to succeed him.

### CORRECTION

**Pathology of Rheumatoid Arthritis.**—In the abstracts of the meeting of the American Rheumatism Association, in the discussion given by Dr. D. Murray Angevine on page 2042 of the November 26 issue, the sentence reading "I trust that we have not given the impression that we feel certain that there is an atypical pathologic picture for rheumatoid arthritis" should have been "I trust that we have not given the impression that we feel certain that there is a typical pathologic picture for rheumatoid arthritis."

#### Medicine and Penal Reform

The criminal justice bill, which has been introduced in the House of Commons by the government, marks a big advance in dealing with young offenders. Institutions to be called "remand centers" are to be provided, to which such offenders when remanded or committed for trial in custody are to be sent instead of to prison. There will also be "remand homes" for problem children and persons under 17 who require medical observation. Offenders between 16 and 21 whose offenses justify a period of Borstal training are to go to institutions called Howard homes, which will exercise a system of residential control, but they will be able to go out to their ordinary employment. There will also be public hostels for young persons who ought to be sent away for a time from their homes or from places where they have fallen into bad associations. Another interesting experiment is the establishment of "compulsory attendance centers," where young persons sentenced for minor offenses may be sent and avoid imprisonment. They will be required to attend during half holidays or in the evening after work.

Another most important reform is abolition of the power of the courts to pass sentences of corporal punishment, which is reserved for serious prison offenses. Others are two new types of prison sentences, corrective training and preventive detention. The former will be for not less than two or more than four years for persons between 21 and 30 whose records make such sentences expedient. Preventive detention is for persons over 30 whose records make this necessary for the protection of the public. Such sentences may range from four to ten years. The Broadmoor institution for criminal lunatics is to be transferred to the management of the board of control, the body which controls the administration of mental hospitals.

This bill, which is the latest development of the modern tendency to make the criminal law more humane by helping to reform instead of simply punishing the offender, does not touch the vexed question of criminal responsibility. The tendency of psychiatrists to regard crime as a form of mental disease is by no means shared by judges and lawyers. At a meeting of the Hunterian Society, the psychiatrist Dr. Henry Yellowlees opened a discussion on the thesis that the psychologic treatment of the criminal is preferable to the punishment of the crime. He said that our penal system was becoming less vindictive, more reformatory and more humane. Society was beginning to recognize its duty to the criminal. The highest expression of that duty lay in regarding him as a mentally sick man. Many an antisocial act was committed under the pressure of an irresistible psychologic force, all the more terrible in that it was not consciously realized. But psychotherapy could not be applied to the whole criminal picture indiscriminately. Some criminals it could not help; it was a failure in the absence of sincere, willing and persistent cooperation of the patient. It was the duty of the law to decide what criminals would respond to the appeal of psychotherapy, but its criteria of criminal responsibility in cases of glaring insanity showed how unqualified it was to decide the matter.

In the discussion, lawyers took part. While they admitted that it would be better for many prisoners to be treated psychologically, that did not mean that they should be sent to a hospital and not to prison. The fear of prison was a valuable deterrent. One claimed that Dr. Yellowlees had killed his own motion. Psychology, he said, had been described as a

science in its infancy, but it was in a prenatal stage, with little prospect of live birth. It had created a terminology and called it a science. The motion was carried by a large majority.

#### THE SOCIAL RELATIONS OF SCIENCE

The formation of an organization to study the social relations of science is proposed in the periodical *Nature*. Forty scientists, including Sir William Bragg (president of the Royal Society), Sir John Russell (director of the Rothamsted Agricultural Station), Sir F. Gowland Hopkins (professor of biochemistry, Cambridge), Prof. J. B. S. Haldane, Julian Huxley, H. G. Wells, and representatives of sociology, economics and psychology, comment on the need to go deeper into the repercussions which science has had on social development. From the platform of the British Association for the Advancement of Science, speakers have repeatedly urged the need for a scientific survey of the problems which confront civilization, problems largely the result of the discoveries of scientific workers. The American Association for the Advancement of Science officially expressed concern that "science and its applications are not only transforming the physical and mental environment of men but are adding greatly to the complexities of the social, economic and political relations among them." One of its representatives is coming over to discuss with the British association the problem of joint action. The International Council of Scientific Unions set up last year a committee to survey the influence of science on the world picture as well as on the material side of human life and society.

Julian Huxley asks "What research is being done in Great Britain, under what conditions and how financed? Why are some branches relatively neglected? What are the trends of research and its practical and social effects?" He visualizes an organization which would supply authoritative information. A code of ethics for scientific men is envisaged by Prof. A. V. Hill, secretary of the Royal Society. Secrecy in research, the patenting of discoveries of public value, advertisement, expert evidence, the exploiting of dangerous knowledge or the selling of dangerous drugs could form the subject matter of such a code.

#### Routine Preoperative Roentgenograms of the Chest

X-ray examination of the chest is employed as a routine in France in the examination of army and navy recruits, medical students, pupil nurses and applicants for government and private employment. This method of examination is simple and should be used in the evaluation of the risk of operative procedures in all hospital services. Professor Sergent of Paris has called attention to the danger of operation when there is pulmonary tuberculosis, and Bezançon and Jacquelin have studied the effect of operations in lighting up latent tuberculous foci in the lungs. A team composed of Professor Gosset, surgeon, Professor Etienne Bernard, phthisiologist, and Professor Ledoux-Lebard, radiologist, decided to examine all patients preoperatively, and the results of eleven instructive observations were submitted at the October 4 meeting of the Académie de médecine. Four of the operations were performed as emergencies and preoperative x-ray examination of the chest was not carried out. The later appearance of fever, cough and expectoration led to such examination after operation. In all four cases there were found advanced tuberculous lesions which had shown evidence of exacerbation after the anesthesia. In five cases preoperative x-ray examination revealed pathologic changes in one or both lungs. In one of these the presence of infiltration at one apex led to postponement of the operation until the pulmonary lesions had

improved. Operation was performed in one with local anesthesia and in one with spinal anesthesia without any ill effects, but in a third, in which general anesthesia was used, there was a marked rise in the temperature after operation and smears of expectorated material showed tubercle bacilli. In the tenth case there was some doubt before operation as to the existence of a pulmonary focus and general anesthesia was employed; it was followed by a marked exacerbation of a latent tuberculous lesion. In the eleventh case the preoperative x-ray examination failed to reveal any pulmonary focus but after operation the presence of a high temperature led to x-ray examination and bacteriologic examination of the sputum, which revealed an infiltration of the base of the right lung and the presence of tubercle bacilli.

The authors said that all patients should be subjected to x-ray examination of the chest as a routine part of the preoperative examination. If a definite focus is found, it is advisable to employ either local or spinal anesthesia or any general anesthetic other than ether. These precautions hold true for emergency operations.

In the discussion Professor Sergent emphasized that, although there are tuberculous foci which are not detected by the ordinary methods of physical diagnosis, there exist lesions which escape detection by x-ray examination. Hence both methods should be employed.

Professor Laubry said that he would enlarge the field of preoperative x-ray examination to include an examination of the heart and large vessels.

#### Action of Sulfanilamide-Pyridine on the Pneumococcus

The many advantages of sulfanilamide-pyridine over the older sulfanilamide was the subject of a paper by Dr. Raymond Benda read at the October 21 meeting of the Société médicale des hôpitaux of Paris. Dr. Benda stated that the newer preparation is far less toxic and that in 151 cases no cyanosis of the lips or nails had been noted. The only ill effects were anorexia, nausea and headache in one case. Dr. Benda reported five cases of pneumococcal infection in which sulfanilamide-pyridine had been given. The temperature of a patient aged 74 with a large area of consolidation became normal and the physical evidence of pulmonary involvement disappeared within forty-eight hours after the administration of 3 Gm. of sulfanilamide-pyridine. In another case both this drug and sulfanilamide had been given at intervals of several weeks, so that their action could be compared. The patient was a man 44 years of age suffering from a pulmonary abscess of pneumococcal origin. During the fourth week a daily dose of 3 Gm. of sulfanilamide had been given for five days without any improvement in the patient's condition. Dr. Benda saw him for the first time twelve days later and advised administration of 3 Gm. of sulfanilamide-pyridine. This was followed by a sharp drop in the temperature, which persisted for five days, but it was necessary to discontinue administration of the drug because of persistent nausea. The temperature rose again and remained up until the sulfanilamide-pyridine was given again twenty days later. After a second drop in the temperature to normal, the general condition improved to such an extent that operative intervention could be undertaken.

#### Streptococcal Empyema Cured by Sulfanilamide

At the same meeting three French naval surgeons, Drs. Germain, le Gallou and Morvan, reported a case of pleurisy on the right side involving the mediastinal aspect of the pleura and complicated by empyema due to the hemolytic streptococcus. Cure without operative intervention followed the use of sulfanilamide by mouth and intramuscular injection combined with evacuation of the pus by repeated punctures and injection of the drug into the pleural cavity.

### Congress of the European Society of Mental Hygiene

The Congress of the European Society of Mental Hygiene was held at Munich late in August under the auspices of the German Committee for Mental Hygiene, a branch of the Society of German Neurologists. Professor Rüdin of Munich presided. The mental hygiene movement is recognized to have originated in America, to have slowly gained headway in other countries after 1905 and to have spread much more rapidly since the World War. The German Association for Mental Hygiene was founded in 1925; it was superseded in 1935 by the mentioned committee. In recent years the latter has stressed the problems of eugenics in conformity with the German national attitude.

Even at this congress of the European organization the first theme of discussion was "The Eugenic Marriage," introduced by Morgenthaler of Berne and Chairman Rüdin. Morgenthaler spoke on the selection of the marriage partner. In his opinion, every healthy person should marry. Conversely, he opposes the marriage of a person who may be classed as incurably a member of one of the following groups: the feeble-minded, the insane, excessively egocentric psychopaths, degenerate hysterics, drug addicts, homosexuals and manifest schizoids. He also is against the marriage of persons unsuited for a tranquil married life because of abnormal aggressiveness, passivity or introversion. More attention should be paid to those persons who, although basically fit for marriage, remain single because of timidity and similar psychic factors. The ministrations of a well regulated matrimonial agency should be of optimal service to this group. The youth should be definitely trained for marriage, and individual advice is desirable.

Rüdin lectured from the standpoint of the eugenic condition and hereditary endowment of the population as a whole. He pointed out that it is the first duty of a family physician who is schooled in eugenics to try to prevent all genetically and nationally undesirable mesalliances. In addition, social intercourse among boys and girls of families presenting hereditary defects and poor hereditary endowment should be deliberately discouraged. The theory that degenerate families can be "regenerated" by union with eugenically healthier persons is today looked on as unmoral and obsolete. It is difficult to make decisions with regard to persons who, although themselves free of hereditary defects, are possessed of tainted kindred. Here one is confronted with one of the most burning questions of genetic research, the heterozygote problem. Diagnostic possibilities as well as statistical data fail here.

In the discussion the importance of eugenics propaganda was ardently championed by two Italians, whereas Repond, a Swiss, urged that decisions with regard to marriage should be made with caution, since the civilized nations of the West have yet to hit on a generally acceptable "formula of marriage." Former Hamburg psychiatrist Weygandt, on the other hand, voiced the opinion that objectives such as the improvement and purification of hereditary characters cannot be attained without the use of force.

At the second session the problem of "Prophylaxis of Drug Addiction" was taken up. Stanojewitsch of Belgrade stated that addiction to narcotics is not an important problem in Yugoslavia. Russian immigrants are largely responsible for an increase in alcoholism as well as morphinism and cocaineism since the World War. Drunkenness is extremely rare among the country's Jewish population. Pohlisch of Bonn discussed the results of modern genetic and constitutional research studies of addicts. He disparaged the "Jewish psychology systems" of Freud and Adler, which attempt to place the responsibility

for the production of addiction on environmentally conditioned injuries to the psyche. He also accused these schools of working mischief by an arbitrary use of the terms "rausch" and "sucht," which tends to obscure and confuse heterogenic concepts. Conversely, research of recent years, based on natural scientific methods, has elicited proof that the circumstances and essential etiologic factors in cases of addiction should be looked for in the domain of endogenic, congenital, psychosomatic hereditary defects. The abnormal familial background of addicts is a matter of voluminous, statistical record of grave congenital defects. Numerous other factors ought not of course to be ignored. Also of interest are the racial-biologic differences which underlie the predilection of various peoples for particular addictions. Because of drastic legal restriction, addiction to opiates has become rather unimportant in Germany. The misuse of hypnotic drugs, on the contrary, should be a serious consideration of the medical profession.

In conclusion Panse spoke on hygienic and legislative measures against drug addiction, and Crime Commissioner Thomas, director of the National Antinarcotic Police Center, described various international measures in this field.

In the general discussion, mention was made of the great decrease in alcoholism in Italy. Fahreddin Kerim Gökey of Istanbul told of the Turkish government's campaign against addiction to drugs. This campaign is all the more noteworthy because these alkaloids represent a source of government income which should not be underestimated. In southern and western Anatolia hasheesh is the usual drug; in Istanbul it is heroin. Morphine and cocaine play minor parts.

Other reports dealt with child psychiatry and child psychology and the importance of occupational therapy in the treatment of mental and bodily illness.

#### The Purge of Jewish Physicians

Supplementary data can now be added to the recent reports on the purge of Jewish physicians (*THE JOURNAL*, September 17, p. 1118, and October 29, p. 1674). September 24 Professor Dr. Klare, "commissioner of the specialized medical press," issued the following statement: "In view of the fact that the German medical profession is now freed of all members of an alien race, the writings of Jewish authors ought not to appear in our German medical journals. At the same time I trust that our German doctors will subscribe only to those foreign journals which are published by Aryan organizations and edited by Aryan physicians. In this connection I should like to call attention to the emigration of the journal *Ars Medici*, together with its Jewish editor and publisher, Dr. Max Ostermann, from Vienna to Switzerland. From its new home this publication continues to solicit the subscriptions of German doctors, but I feel sure that our men will refuse to have anything to do with the Jewish publisher of *Ars Medici*." The mentioned periodical had circulated widely among practitioners within the German reich.

With respect to Jews in the insurance panel practice, it has been newly decreed that those Jews who have been allowed to continue in medical practice (under the restrictions described in previous letters) may now take part in panel practice among insured Jews and their families; a special permit is needed for panel practice.

That, actually, a definite lack of physicians has resulted from the suppression, since October 1, of Jewish doctors is evidenced by the recent establishment of "policlinic treatment centers" at seventeen municipal clinics of Berlin. These centers are designed for the exclusive use of members of sickness insurance clubs and patients referred by the social service agencies; in other words, just those groups which are usually treated by the panel practitioners. It was expressly stated that these auxiliary centers were designed to lighten the load

of the panel doctors (a new consideration). The medical staffs of fourteen municipal emergency stations were also increased for the same purpose as well as for emergency house visit duty, especially at night. Meanwhile it has been decreed that the foregoing measures shall be discontinued November 16.

#### ITALY

(From Our Regular Correspondent)

Nov. 15, 1938.

#### Registrations in Universities Limited

The minister of national education fixed the number of registrations in the universities of Rome and Naples for the year 1938-1939 at a maximum of 15,000 and 10,000 respectively. The action was taken to prevent a plethora of students and to make the theoretical teaching and laboratory work more profitable. The criteria to be followed in accepting applications for registration will be fixed by the personnel of the universities in agreement with the opinions of the minister of education. Residents in the city will be given the preference over nonresident applicants.

#### Treatment of Fractures of Limbs

Professor D'Agata of the University of Messina lectured before physicians of the army on modern trends of military surgery. He said that when reduction of a fracture cannot be done satisfactorily at a first aid station, especially in war, it is advisable to apply a Thomas or metallic Cramer splint or a similar apparatus for temporary immobilization. The good position of the fragments is controlled by x-ray examination. Application of large casts in which the proximal and distal joints are included is not advisable. Immobilization is applied only over the focus of the fracture, leaving the limb in a position of rest and, if possible, leaving all the joints free. These conditions can be obtained by traction with the limb, especially the leg, in a double-inclined plane. Adhesive plaster or a bandage with Unna's paste (zinc oxide, glycerin and mucilage) is resorted to when traction is applied to the soft parts. Direct traction on the skeleton can be done by means of wire (Kirschner and Klapp's method) or a nail through the calcaneus. The patient with a fracture of the leg is asked to do certain walking after consolidation of the immobilizing apparatus, as walking stimulates consolidation and prevents rigidity of the joint. For an open fracture some surgeons advise treating first the wound and then the fracture, whereas others follow the inverse order. In first aid stations it is advisable to limit the treatment to cleansing the wound, temporary immobilization of the limb without reduction of the fracture, and bandaging the wound. The patient is immediately transported to a surgical center so that he may have proper treatment during the first four or six hours after trauma.

#### Meeting of Academy in Florence

The Accademia Medico-Fisica of Florence recently met. Dr. Ferranti spoke on the value of electrocardiography in the diagnosis of coronary insufficiency. He said that only the monophasic wave and the coronary wave, which is a proper wave of myocardial infarct, are of precise diagnostic value. A Q<sub>s</sub> wave of the Willins type in patients with precordial pain shows the presence of Roemheld's syndrome rather than coronary insufficiency. It depends on a transverse position of the heart. A depression of the S-T segment or an inversion of the T wave may be due to hypertrophy of the right or the left ventricle. The simultaneous presence of other signs of predominance of either ventricle shows ventricular origin, whereas their absence shows coronary origin. The tests for diagnosis of coronary functions are of little value. The speaker advised a careful study of the electrocardiograms for a precise interpretation of diagnostic value.

Dr. Bretta said that he followed the behavior of the potassium-calcium ratio of the blood of normal persons after administration

of a large dose of insulin. Calcemia increased and potassemia diminished in disruption of the equilibrium of the sympathetic over the vagal stimulation. The speaker believes that the sympathetic disequilibrium is the cause of the disturbances of circulation of diabetic patients in the course of insulin therapy.

#### New Type of Malignant Granuloma

Professor Freund, in a lecture recently delivered to the Associazione Medica Triestina, spoke on a new type of Sternberg lymphogranuloma. He reviewed Oberling's classic experiments on leukemia in chickens and the identification of the virus in the disease. He reported three cases of grave fungoid mycosis, a case of lymphocytoma and a case of malignant lymphogranuloma of Sternberg's type. His case and two cases reported from France in 1917 form the group of cases of a new type of malignant lymphogranuloma which is generally called perioral eosinophilic granuloma.

### POLAND

(From Our Regular Correspondent)

Nov. 27, 1938.

#### Reaction of Physicians to the New Medical Law

As reported some months ago, the number of physicians in Poland is much too small in proportion to the total population. There is a remarkable want of medical service in the villages, as most of the physicians are concentrated in large cities. This fact has long been considered by the medical authorities. Some months ago a bill was passed by the Polish diet aimed at satisfying the health demands of the country, according to which every physician who graduates after April 1, 1939, will be allowed to practice in large cities only after he has practiced for two years in towns of less than 5,000 inhabitants. The law caused a strong reaction among physician and student organizations. A deputation of the general medical council, with its president, Prof. Mieczysław Michałowicz, received by the prime minister, claimed that the law will fail to obtain any positive improvement in the state of medical service in villages. Moreover, it will deter the youth from medical careers, as no financial aid for physicians obliged to practice in villages has been provided. Furthermore, the law will infringe on the right of every adequately qualified physician to practice anywhere in Poland. The students, in protest, stopped attending lectures for three days. The strike broke out last week in faculties of medicine all over Poland.

#### Organization of Medical Aid for Jewish Refugees

At the German-Polish frontier many thousands of Jewish refugees from Germany have been arrested by the Polish authorities. The refugees have lived under very bad hygienic conditions and have been exposed to undernutrition and atmospheric influences. The society for the health protection of the Jewish population in Poland, "TOZ," under the management of Dr. L. L. Wulman, has organized free medical aid for the refugees. A hospital was established at the frontier with an isolation ward for patients with infectious diseases and three infirmaries for outpatients. The staff consists of fifteen physicians. In the last weeks over 16,000 patients have been attended. There were 1,139 with influenza, 1,065 with catarrhal disorders of the respiratory tract, 829 with sore throat, 709 with rheumatism, 513 with peptic disorders, 349 with cardiac disorders and fourteen with mental disorders.

#### A New Medical School

When the question of obligatory practice in villages was taken up, the diet decided to take other measures to satisfy the demands for medical service and to raise the number of physicians. There are five universities with faculties of medicine, and the government proposed to establish a medical school in Lodz, a city of more than 500,000 inhabitants, which has

had no university. The project was welcomed by the inhabitants of Lodz, and a committee was organized to supply financial aid for the founding of the school. The antisemitic organizations of students of medicine in other cities, however, passed a resolution protesting against the establishing of the school, claiming that it would increase the percentage of Jews in the medical profession, since there are many Jews in Lodz and the committee is supported financially by Jewish philanthropists. This action of the antisemitic students is held by democratic groups to be a handicap in the supplying of sufficient medical aid to the country. In spite of it the building of the new medical school will begin shortly.

#### Treatment of Bronchial Asthma with Insulin Shock

Dr. Z. Askanas of Warsaw recently reported on the treatment of bronchial asthma by the method of Dr. Węgieńko, of Warsaw University, a method based on the observation that hypoglycemic shocks provoked by insulin control attacks of dyspnea in cases of bronchial asthma and diminish the disposition to recurrence. The effectiveness of the treatment is attributed not to the action of insulin itself but to the desensitizing effect of the hypoglycemic shocks. The author administered subcutaneously 40 units of insulin with the patient's stomach empty. The first manifestation of shock appeared in about forty-five minutes as a sensation of heat and a slight tremor of the hands. In from seventy to ninety minutes other features of shock appeared: tremor of the limbs, great hunger, profuse perspiration, a decrease in the pulse rate, a slight decrease in the arterial pressure and in the temperature and hyperreflexia. Sometimes the patient complained of palpitation of the heart or uneasiness. Great relief from the dyspnea was obtained soon after the early manifestations of shock had appeared. Some minutes later the dyspnea stopped entirely. The shock was stopped in from thirty to sixty minutes by the oral administration of large doses of sucrose solution, bread, honey, cakes and fruits. An immediate stopping of the shock can be obtained by intravenous injection of 20 to 40 per cent dextrose solution. To obtain improvement for a longer time, the author repeated the shocks every one to three days. The whole treatment consisted of from five to seventeen shocks.

In fifty-eight of sixty-five cases, great improvement was obtained. The attacks of dyspnea have not reappeared in from ten months to three years after treatment. Shock therapy failed to achieve permanent results when the bronchial asthma was associated with extensive pulmonary emphysema or serious endocrine disorders or was related to focal infection. There were seven cases of such asthma in the series. Shock therapy is the method of choice for asthma related to emotional disturbances, allergy, functional endocrine disorders and, especially, asthma in children. Even when permanent relief was not obtainable there was prompt control of the dyspneic attack in all cases.

## Marriages

THOMAS HAMILTON HOGSHEAD, Staunton, Va., to Miss Catherine Louise Gierhart of Yonkers, N. Y., in September.

AMOS GILMORE CRUMPLER, Fuquay Springs, N. C., to Miss Dorothy May Raine of Royersford, Pa., August 26.

FRANK RANDOLF PHILBROOK, Randolph, Mass., to Miss Madeline Hartford of Berwick, Maine, July 2.

ROBERT B. J. . . . . Ind., to Miss Ida Wood of Spencer in . . . . . 10.

THOMAS D. THOMPSON to Miss Martha Simons, both of Spokane, Wash., August 26.

RICHARD COLLINS JR., Waltham, Mass., to Miss Jean Chapman of Lincoln, August 26.

THOMAS E. BYRNE, Mentor, Ohio, to Miss Alice G. Mullen of Madison, Wis., recently.

## Deaths

**George Burgess Magrath**, Boston; Harvard University Medical School, Boston, 1898; member of the Massachusetts Medical Society; medical examiner of Suffolk County, 1907-1935; professor of legal medicine, emeritus, at his alma mater and at various times assistant in pathology, assistant in hygiene and instructor in legal medicine; was the first incumbent of a new chair of legal medicine established in 1932 at Harvard University, an appointment made on his twenty-fifth anniversary of service as county medical examiner; in 1934 the George Burgess Magrath Library of Legal Medicine at Harvard was dedicated in his honor; lecturer at the Lowell Institute; pathologist to the Long Island Hospital, 1898-1905, and the Carney Hospital, 1900-1905; co-author of "Studies in Variola and Vaccinia," 1903; aged 68; died, December 10, in Massachusetts General Hospital, Phillips House, of cerebral hemorrhage.

**Joseph Addison Crowell** Ⓢ Iron Mountain, Mich.; University of the City of New York Medical Department, 1881; fellow of the American College of Surgeons; past president of the Dickinson-Iron Counties Medical Society; formerly mayor, and member of the board of education; was chairman of an exemption board during the World War; aged 84; on the staff of the Iron Mountain General Hospital, where he died, October 22, of injuries received when he fell into the basement while the trap door was open.

**Richard Cecil Smith** Ⓢ Superior, Wis.; Washington University School of Medicine, St. Louis, 1911; member of the American Academy of Ophthalmology and Oto-Laryngology and the Pacific Coast Oto-Ophthalmological Society; fellow of the American College of Surgeons; ophthalmologist to St. Mary's, St. Francis and Good Samaritan hospitals; aged 52; died, October 30, of coronary occlusion.

**Louis Anthony Meraux**, New Orleans; Medical Department of Tulane University of Louisiana, New Orleans, 1904; member of the Louisiana State Medical Society; for many years sheriff of St. Bernard parish; at one time parish health officer; aged 58; died, October 6, in the Hotel Dieu, Sisters' Hospital, of coronary thrombosis, diabetes mellitus and carbuncle of the neck.

**Owen Taylor**, Kent, Wash.; Bellevue Hospital Medical College, New York, 1895; member of the Washington State Medical Association; fellow of the American College of Surgeons; served during the World War; on the staff of the Suburban Hospital, Auburn, formerly known as the Owen Taylor Hospital; aged 71; died, October 3.

**Arthur Alston Morrison** Ⓢ Savannah, Ga.; University of Georgia Medical Department, Augusta, 1923; fellow of the American College of Surgeons; chairman of the city council; on the staffs of the Warren A. Candler Hospital, St. Joseph's Hospital and the Georgia Infirmary; aged 38; died, October 17, of coronary occlusion.

**Jerome Francis Smersh** Ⓢ Owatonna, Minn.; University of Minnesota Medical School, Minneapolis, 1917; fellow of the American College of Surgeons; president of the board of health; served during the World War; aged 46; on the staff of the Owatonna City Hospital, where he died, October 26, of pneumonia.

**Richard Milo Olin**, East Lansing, Mich.; University and Bellevue Hospital Medical College, New York, 1899; member of the Michigan State Medical Society; state commissioner of health, 1917-1927; director of the health service, Michigan State College; aged 63; died, October 4, of coronary thrombosis.

**Charles Simpson**, Southbridge, Mass.; M.B., Laval University Medical Faculty, Montreal, 1903, and M.D. in 1904; member of the Massachusetts Medical Society; chairman of the board of health and school physician; on the staff of the Harrington Memorial Hospital; aged 61; died, October 12.

**Alfred Edwin Rhein**, Terre Haute, Ind.; Eclectic Medical Institute, Cincinnati, 1906; University of Illinois College of Medicine, Chicago, 1913; member of the American Academy of Ophthalmology and Oto-Laryngology and the Indiana State Medical Association; aged 55; died, October 21.

**William Humphrys Miller**, Terre Haute, Ind.; Northwestern University Medical School, Chicago, 1907; member of the Indiana State Medical Association and the American Academy of Ophthalmology and Oto-Laryngology; on the staff of the Union Hospital; aged 56; died, October 4.

**Japheth Edward Rawls** Ⓢ Suffolk, Va.; University and Bellevue Hospital Medical College, New York, 1899; fellow

of the American College of Surgeons; aged 63; medical superintendent of the Lakeview Hospital, where he died, October 14, of injuries received in an automobile accident.

**Alvin Raymond Moses** Ⓢ Charlton, Mass.; Tufts College Medical School, Boston, 1920; member of the New England Obstetrical and Gynecological Society; on the staff of the Harrington Memorial Hospital, Southbridge; aged 42; died, October 13, in a hospital at Worcester of pneumonia.

**John Manifold Wallace**, Lynn, Ind.; Medical College of Indiana, Indianapolis, 1903; member of the Indiana State Medical Association; served during the World War; aged 60; died, October 31, in the Randolph County Hospital, Winchester, of injuries received in an automobile accident.

**Robert Pillow**, Columbia, Tenn.; University of Pennsylvania Department of Medicine, Philadelphia, 1874; member of the Tennessee State Medical Association; at one time member of the board of education, mayor and health officer; aged 86; died, October 25, of pulmonary edema.

**Charles Dearborn McDonald**, Boston; Boston University School of Medicine, 1901; served during the World War; member of the Veterans' Administration; aged 63; died, October 20, in the Walter Reed General Hospital, Washington, D. C., of arteriosclerosis and heart disease.

**Arthur Churchill Shamblin**, Cartersville, Ga.; Grant University Medical Department, Chattanooga, Tenn., 1892; member of the Medical Association of Georgia; county commissioner of health; served on a draft board during the World War; aged 67; died, October 23, in Erick, Okla.

**Thomas J. Brown**, Grenada, Miss.; Memphis (Tenn.) Hospital Medical College, 1886; member of the Mississippi State Medical Association; city and county health officer; aged 76; on the staff of the Grenada (Miss.) General Hospital, where he died, October 10, of cardionephritis.

**William Kennedy Butler** Ⓢ Washington, D. C.; Columbian University Medical Department, Washington, 1882; professor emeritus of ophthalmology at the George Washington University School of Medicine; member of the American Ophthalmological Society; aged 81; died, October 17.

**John Webb Simmons**, Martinsville, Va.; Medical College of Virginia, Richmond, 1885; member of the Medical Society of Virginia; for many years county coroner; aged 79; died, October 13, in a hospital at Roanoke of hypertensive arteriosclerotic heart disease and nephritis.

**William Adam Wehe** Ⓢ Topeka, Kan.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1893; aged 69; on the staffs of St. Francis Hospital and the Stormont Hospital, where he died, October 1, following an operation for carcinoma.

**Ewan Alexander Robertson** Ⓢ Newton, Mass.; Chattanooga (Tenn.) Medical College, 1905; member of the New England Society of Psychiatry; medical superintendent and owner of the Woodlawn Sanitarium; aged 73; died, October 18, of coronary thrombosis.

**Charles Torrence Nesbitt**, Wilmington, N. C.; Baltimore Medical College, 1893; formerly city and county health officer, and health officer of Akron, Ohio; at one time surgeon in the U. S. Public Health Service reserve; aged 68; died, October 10, of myocarditis.

**J. Alphonse Sampite**, Cloutierville, La.; Medical Department of Tulane University of Louisiana, New Orleans, 1902; member of the Louisiana State Medical Society; for many years member of the parish school board; aged 59; died, October 11, in New Orleans.

**Charles Edgar Smith**, Mart, Texas; University of Texas School of Medicine, Galveston, 1905; member of the State Medical Association of Texas; formerly secretary of the McLennan County Medical Society; aged 60; died, October 22, of heart disease.

**Thomas Lester Waggoner**, San Angelo, Texas; Baylor University College of Medicine, Dallas, 1930; member of the State Medical Association of Texas; health director of six districts; aged 34; was found dead, October 30, of a self-inflicted bullet wound.

**Willard W. Nye**, Hiawatha, Kan.; Jefferson Medical College of Philadelphia, 1877; member of the Kansas Medical Society; for many years county health officer; Civil War veteran; aged 92; died, October 19, of arteriosclerosis and myocarditis.

**Fred Bennett Colby** Ⓢ Gardner, Mass.; Dartmouth Medical School, Hanover, N. H., 1896; formerly city physician, and member of the board of health; on the staff of the Henry Heywood Memorial Hospital; aged 69; died, October 6, of heart disease.

**Arthur Shaw McDaniel**, San Antonio, Texas; Medical College of Ohio, Cincinnati, 1882; Bellevue Hospital Medical College, New York, 1890; member of the State Medical Association of Texas; aged 82; died, October 18, of chronic myocarditis.

**Donald Alpine McGregor** ☉ St. George, Utah; Barnes Medical College, St. Louis, 1903; fellow of the American College of Surgeons; medical superintendent of the Washington County Hospital; aged 62; died, October 11, of coronary thrombosis.

**Martin C. Bergheim**, Hawley, Minn.; University of Minnesota Medical School, Minneapolis, 1920; member of the Minnesota State Medical Association; aged 52; died, October 4, in St. Ansgars Hospital, Moorhead, of bronchopneumonia.

**John Maxson Brown Wainright**, Jersey City, N. J.; Columbia University College of Physicians and Surgeons, New York, 1904; on the staffs of the St. Francis and Fairmont hospitals; aged 58; died, October 20, of heart disease.

**Frederick Benjamin Schneerer**, Deadwood, S. D.; Bennett College of Eclectic Medicine and Surgery, Chicago, 1903; veteran of the Spanish-American War; on the staff of St. Joseph's Hospital; aged 61; died recently.

**Frank Wesley Nagler**, Yakima, Wash.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1900; member of the Washington State Medical Association; aged 72; died, October 8, of heart disease.

**William Edgar Thomas**, Greensburg, Ind.; Medical College of Indiana, Indianapolis, 1901; member of the Indiana State Medical Association; aged 61; died, October 1, of angina pectoris, arteriosclerosis and hypertension.

**Frederick Capin Bowman**, Duluth, Minn.; Hahnemann Medical College and Hospital of Philadelphia, 1881; formerly member of the board of education; aged 89; died, October 4, of cerebral hemorrhage and hypertension.

**William Scott McKell** ☉ Chillicothe, Ohio; University of Colorado School of Medicine, Denver, 1913; on the staff of the Chillicothe Hospital; aged 55; was found dead, October 17, of chronic valvular disease of the heart.

**Stanislaus A. Bouvier**, Moosup, Conn.; Victoria University Medical Department, Coburg, Ont., Canada, 1889; aged 74; died, September 16, of arteriosclerosis, cerebral hemorrhage and chronic prostatic hypertrophy.

**Benjamin Kelly Simmons**, Blakely, Ga.; Atlanta School of Medicine, 1907; Georgia College of Eclectic Medicine and Surgery, Atlanta, 1910; member of the Medical Association of Georgia; aged 68; died, October 7.

**Charles Chamberlayne Kingsley Phelps**, Sackets Harbor, N. Y.; Bellevue Hospital Medical College, New York, 1898; member of the Medical Society of the State of New York; aged 68; died, September 26.

**Theodore Toy Donaldson**, Powell, Ohio; Ohio State University College of Medicine, Columbus, 1929; member of the county board of health; aged 33; died, October 4, of coronary occlusion.

**John Pierre Nalbant**, Plymouth, Mich.; University of Michigan Medical School, Ann Arbor, 1928; aged 38; died, October 3, in the University Hospital, Ann Arbor, of carcinoma of the cecum.

**Avla Earl Snyder** ☉ Bryan, Ohio; Jefferson Medical College of Philadelphia, 1894; served during the World War; aged 69; died, October 20, in Crystal Lake, Mich., of coronary occlusion.

**Willard T. Nichols**, Milwaukee; Northwestern University Medical School, Chicago, 1894; member of the State Medical Society of Wisconsin; aged 73; died, October 22, of coronary thrombosis.

**Andrew Fletcher Weathers**, Shellman, Ga.; Vanderbilt University School of Medicine, Nashville, Tenn., 1894; member of the Medical Association of Georgia; aged 68; died in October.

**John Harvey Saylor** ☉ Marion, Kan.; Kansas City (Mo.) Medical College, 1904; county health officer; aged 72; died, October 17, in Christ's Hospital, Topeka, of mesenteric thrombosis.

**Ira T. Roberts**, Johnston City, Ill.; St. Louis College of Physicians and Surgeons, 1902; aged 59; died, October 26, in St. Andrew's Hospital, Murphysboro, of cerebral hemorrhage.

**Seine Bolks De Pree**, Sioux Center, Iowa; Rush Medical College, Chicago, 1903; served during the World War; aged 65; died, October 3, of carcinoma of the colon with metastasis.

**Stonewall Jackson Smock**, La Grange, Ky.; University of Louisville Medical Department, 1893; served during the World War; aged 72; died, October 1, of carcinoma.

**Louis Edward Dionne**, Ware, Mass. (licensed by years of practice); for many years chairman of the board of health; aged 74; died, October 16, of cerebral hemorrhage.

**Theodore C. Baumhauer** ☉ Uriah, Ala.; University of Pennsylvania Department of Medicine, Philadelphia, 1903; aged 58; died, October 9, of coronary thrombosis.

**Franklin Seymour Watterworth**, Detroit; Detroit College of Medicine, 1901; on the staff of St. Mary's Hospital; aged 61; died, October 5, of cerebral hemorrhage.

**Charles Henry Christian**, Austin, Texas; Meharry Medical College, Nashville, Tenn., 1914; aged 47; died, October 3, of uremia, chronic nephritis and myocarditis.

**George Averill Tolman**, Detroit; Medical School of Maine, Portland, 1893; aged 71; died, October 14, of carbon monoxide poisoning, self administered.

**John Edgar Rooks**, Shreveport, La.; University of Maryland School of Medicine, Baltimore, 1905; aged 63; was killed, October 18, in an automobile accident.

**George William Racey**, Park Hill, Ont., Canada; University of Toronto Faculty of Medicine, 1907; aged 56; died, October 13, in an automobile accident.

**Robert Mills Smith**, Camden, N. J.; Chicago Homeopathic Medical College, 1904; aged 71; died, October 30, of myocarditis and hypostatic pneumonia.

**William Marion Bryant**, Albany, Ga.; Meharry Medical College, Nashville, 1902; aged 64; died, October 11, in the Phoebe Putney Memorial Hospital.

**John Lee Lantz**, Kansas City, Mo.; Missouri Medical College, St. Louis, 1893; aged 74; died, October 20, in the Research Hospital of coronary thrombosis.

**Clifton B. Olds**, Chicago; Hahnemann Medical College and Hospital, Chicago, 1905; aged 72; died, October 31, following an operation for perforated ulcer.

**Thomas C. Nichols**, Falmouth, Ky.; University of Louisville Medical Department, 1873; aged 89; died, October 8, of diabetes mellitus and myocarditis.

**Kate E. Lozier**, Washington, D. C.; Columbian University Medical Department, Washington, 1895; aged 84; died, October 24, of bronchitis and pneumonia.

**John T. McMath**, Strong, Ark.; University of Arkansas School of Medicine, Little Rock, 1905; aged 58; died, October 26, of carcinoma of the lung.

**Orvis E. Biggs** ☉ Hot Springs National Park, Ark.; Barnes Medical College, St. Louis, 1908; aged 62; died, October 17, of coronary thrombosis.

**Ralph William Steele**, Fayetteville, Ark.; University of Arkansas School of Medicine, Little Rock, 1916; aged 48; died, October 8, of nephritis.

**John Folta** ☉ Ceylon, Minn.; University of Minnesota Medical School, Minneapolis, 1929; aged 37; died suddenly, October 14, of coronary sclerosis.

**Henry Stoesser**, Woodhaven, N. Y.; Eclectic Medical College of the City of New York, 1898; aged 76; died, September 26, of arteriosclerosis.

**Dennis Maxwell Smith**, Madsen, Ont., Canada; Queen's University Faculty of Medicine, Kingston, 1933; aged 30; died, October 30, of burns.

**Charles Franklin Spalding**, Springfield, Mass.; Columbus Medical College, 1886; aged 79; died, October 7, in the Wesson Memorial Hospital.

**John MacQuat Drew**, Lachute, Que., Canada; University of Edinburgh Faculty of Medicine, Scotland, 1911; aged 58; died, September 13.

**Warren J. Hall**, Oakfield, Ga.; Atlanta Medical College, 1885; member of the Medical Association of Georgia; aged 84; died, September 16.

**Alexander M. McCreary**, Poland, Ohio; Eclectic Medical Institute, Cincinnati, 1876; formerly mayor; aged 87; died, September 26.

**James Henry Roth**, Chicago; Rush Medical College, Chicago, 1895; aged 70; died, October 1, of cerebral hemorrhage.

**John Henry Cox**, Lucasville, Ohio; Eclectic Medical Institute, Cincinnati, 1889; aged 85; died, October 20, of senility.

**Marvin A. Nunn**, Halls, Tenn.; Memphis Hospital Medical College, 1901; aged 59; died, October 31, of pneumonia.

**C. J. Curry**, Benton, Ark. (licensed in Tennessee in 1889); aged 78; died in September.

## Bureau of Investigation

### THE INTERSTATE SERVICE

#### Exploiting Prescriptions for Complaisant Physicians

The vagaries of the mail-order business are axiomatic: now comes a concern known as the Interstate Service at 111 West Jackson Boulevard, Chicago, which appears to be writing to physicians with the hope of developing private prescriptions into nostrums. One paragraph of the promotional letter reads:

"How often have you thought of a favorite and unusually effective prescription that you would like to make available to the general public? One that could take its place with many of the proprietary preparations now generally on sale. Each of us cherishes some life long ambition and only the lack of opportunity prevents the fruition of long deferred plans. Ask yourself this question and determine right now whether any further delay is necessary."

This attempt to win doctors to commercial exploitation of their prescriptions is a strange type of seduction. Another section of the letter reads:

"Let each specialist keep within his field. And only by collaboration can the greatest good be achieved. We address you, a physician, as specialists in the field of mail-order selling. And, as such, we say that the cost of launching such a venture is moderate. You provide the formula. It is our business to help sell it for you."

And, as a final shot in the dark, the letter closes with the following plea:

"These are days when additional sources of income should not be overlooked. Why content yourself with a vague hope and a further promise to do something about that formula 'some day.' Please drop us a note requesting further particulars."

No reputable physician would, of course, lend his services, knowledge or personal treatment to such a performance. It is a peculiar form of stupidity that would lead a promoter to put out such an appeal at a time just after the new Wheeler-Lea and Food and Drug legislation have been passed. It is sad to think that there might be some physicians who would consider participation in such an unscientific and unethical venture.

### THE R. W. McCLINTOCK FRAUD

#### Research Laboratories Foundation Debarred from the Mails

"McClintock's Formula for Diabetes," "Sto-Bo-Ki" for "stomach sufferers" and "McClintock's Kidney and Bladder Sterilizer" were three mail-order fakes sold by a quack, one R. W. McClintock, who did business under the imposing trade styles "Research Laboratories Foundation" and "McClintock's Laboratories" at Ann Arbor, Mich. On July 14, 1938, the Postmaster General issued a fraud order closing the mails to McClintock and his two trade names. The information that follows is based partly on the memorandum of Hon. W. E. Kelly, acting solicitor for the Post Office Department, to the Postmaster General, and partly on material in the files of the Bureau of Investigation of the American Medical Association.

In 1933 the McClintock's Laboratories, then conducted from the Insurance Exchange Building, Detroit, was advertising ("for Adults Only") what were termed "60 Jewels of Life—A Safe and Effective 30 Day Treatment for Nerves and Glands Resulting in Happy, Normal Life." Price \$6.

In 1934 the McClintock fakery had moved to Ann Arbor and was featuring three nostrums: "Sto-Bo-Ki" for "stomach trouble," "Ex-Fre" for skin disorders and "McClintock's Whooping Cough Formula." At that time Sto-Bo-Ki was McClintock's *opus major* and testimonials with names and addresses were part of the advertising. Thus, Mr. Charles G. Lindner of New Castle, Pa., claimed to have cured himself of a long-standing case of duodenal ulcer with one bottle of Sto-Bo-Ki; Mr. Charles Estenberg of Detroit testified that he and his wife were both "completely cured of a bad stomach condition"; Mr. Donald Kirkendall, also of Detroit, claimed to have "entirely recovered" from "kidney trouble," from which he suffered for many years, after taking one bottle of Sto-Bo-Ki.

In 1936 Sto-Bo-Ki was being recommended as a cure for diabetes; later (1937-1938) McClintock was ballyhooing what he called his "Formula for Diabetes." The apparent discrepancy was cleared up by the analyses made by government chemists

for the Post Office Department; Sto-Bo-Ki the stomach remedy and McClintock's Formula for Diabetes were apparently the same thing! Each was found to be essentially a solution of free sulfuric acid and ethylsulfuric acid in alcohol flavored with cinnamon and ginger. In other words, the Aromatic Sulfuric Acid (Acidum Sulfuricum Aromaticum) of the U. S. P. and B. P. This may account for the claim made by McClintock in 1934 for Sto-Bo-Ki, before he decided to sell the same thing under two names for two widely different conditions. At that time he advertised Sto-Bo-Ki, in part, as follows:

"For this resultful remedy is the heritage of a family of famous physicians and chemists. The formula was discovered more than seventy-five years ago and is recorded in both the English and U. S. Pharmacopeia. More than twenty physicians and chemists, descendants of the discoverer, have guarded and handed down this precious formula from one generation to another. Today Robert McClintock, a direct descendant, controls the formula. This is STO-BO-KI, which is registered with the Pure Food and Drug Administration at Washington, D. C. . . ."

In a 1938 advertising leaflet McClintock declared that his "Formula for Diabetes" was "Registered with the United States Pure Food and Drug Administration and also the United States and British Pharmacopeias." In recent years McClintock developed caution in publishing what he declared were testimonials. No names or addresses were given other than such vague identification as "W.H.S. — Michigan," "K.C. — Georgia" and "L.I.H. — Pennsylvania."

McClintock is not a physician. According to the solicitor's memorandum McClintock claimed to be a chemist but no evidence appears in the record to substantiate the claim. McClintock also claimed—according to the memorandum—that he discovered the diabetes remedy (Acid. Sulf. Arom., U. S. P.) while his grandfather discovered Sto-Bo-Ki (also Acid. Sulf. Arom., U. S. P.)! McClintock offered no medical testimony in behalf of his nostrums but, as shown, did submit a number of testimonials. In this connection it is worth repeating what a former attorney general for the Post Office Department said a few years ago after having heard a large number of cases of medical mail-order fraud:

"Speaking generally it may be said that in all my experience in this office never has a medical concern, no matter how fraudulent its methods or worthless its treatment, been unable to produce an almost unlimited number of these so-called testimonials letters."

For a time McClintock had associated with him in what he claimed was an "advisory capacity" a Dr. C. B. Stouffer, who got out from under in March 1938. It was on April 29 that the Post Office officials served notice on McClintock to show cause why a fraud order should not be issued against him and his schemes. In fact, Dr. Stouffer's name was included in the list of those against whom the Post Office brought charges. According to the biographic files of the American Medical Association, Dr. Stouffer was born in 1878, received a diploma from the University of Michigan Homeopathic Medical School in 1913 and in the same year obtained licenses to practice in Michigan and Maryland. He is not a member of the American Medical Association. As Dr. Stouffer was no longer connected with McClintock's quackery when the fraud order was issued in July 1938, his name was not included in the order.

To physicians familiar with the pathology of diabetes and of stomach and duodenal ulcer (for which McClintock's nostrums

#### McClintock's Formula For Diabetes

Scientific — Ethical — Reliable

IT MAY seem strange to persons who have always heard and believed that there was no cure for Diabetes to learn now that McClintock's Formula for Diabetes never has failed in a single instance to give satisfactory results.

Just as the old theory of starving typhoid patients has been reversed through scientific research to feeding them, we, too, have found a new method of treating diabetes. This method is the result of years of scientific laboratory tests which have shown us that the presence of sugar in the urine is the result, and not the cause of diabetes. And upon this cause, we have spent a lifetime of investigation in our laboratories.

So science again has moved a step forward in the ranks of progress. It has revolutionized the old theory of the insulin needle and starvation, to regular diet and the readjustment of the digestive organs.

were recommended) the viciousness of the claims made for these products is obvious. But to those without medical knowledge the claim that the diabetic patient by using McClintock's nostrum could "eat a normal meal" and the further claim that the preparation "never had failed in a single instance to give satisfactory results" might readily lead to serious if not fatal results. The public once more has to thank the Post Office Department for protecting it against a cruel fraud by declaring that the McClintock scheme was one for obtaining money through the mails under false and fraudulent pretenses, representations and promises, and by closing the mails to it.

According to the evidence submitted at the Post Office hearing McClintock obtained his victims by "advertisements respecting his preparations being placed in various periodicals." The inevitable hook-up between certain publishers and quacks.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

PROBABLE BRAIN ABSCESS AND SYMPATHETIC MENINGITIS

To the Editor:—A sailor aged 23 was admitted to a hospital July 15, 1938, complaining of headache, fever and rigidity of the neck. The present illness started eight days before admission as persistent left-sided headache and moderate fever. The following day the headache became more intense and the fever higher; he had attacks of vomiting for two days and complained of rigidity of his neck and pain whenever he

tried to bend his head and of pains in the lumbar region radiating to both lower extremities. Together with these symptoms he also noticed an increase of the purulent discharge from that ear. He had been having purulent discharges from both ears off and on for nine months. One year and five months ago he was accidentally struck in the head with a piece of lumber, which rendered him unconscious for two days. On regaining consciousness he had paresis of the left half of the body, which gradually disappeared almost completely after five months' treatment except for slight weakness of the left lower extremity. The patient was highly febrile (39.2 C., 102.5 F.) on admission but was conscious; tenderness was elicited at the exit of the cranial nerves; the neck was rigid; the knee jerks were exaggerated; Kernig's sign was positive. The ears showed central perforation of the drum membrane, about 2 mm. in diameter, with a slight purulent discharge. There was no sagging of the posterosuperior wall of the auditory canal and no mastoid tenderness. Hearing tests showed slight conductive deafness. The vestibular tests showed normal reaction to turning and caloric tests. Examination of the blood July 15 revealed total leukocytes 21,400 per cubic millimeter, neutrophils 84 per cent, lymphocytes 12 per cent, mononuclears 4 per cent, eosinophils 0, basophils 0. The urine was normal. Blood culture July 20 was negative. Culture from the cerebrospinal fluid July 18, July 20 and August 3 was negative. The report of an x-ray examination of the mastoids July 18 stated that no definite opinion could be given. Culture from the nasopharynx July 25 was negative for meningococci and positive for Staphylococcus albus and aureus and diphtheroids. Treatment consisted of repeated lumbar puncture, the administration of sodium salicylate and methenamine and hypodermoclysis with isotonic dextrose solution. The fever soon abated; four days after admission the patient was afebrile and has remained so ever since. The headache and rigidity of the neck rapidly disappeared. The discharge from the ear also rapidly decreased even though the ear was not treated. However, up to the present time (August 20) slight weakness and numbness of the left lower extremity has remained. I should like to know your diagnosis of the case. Failure to isolate any organism from the cerebrospinal fluid naturally made the diagnosis difficult and speculative. Is it a case of purulent meningitis of otitic origin? If so, how did the infection get into the subarachnoid

space? There were definitely no signs of mastoiditis, labyrinthitis or other septic focus in the temporal bone. The symptoms of meningitis were not preceded with pain and increased discharge from the ear. Don't you think that the purulent meningitis was probably due to organisms which entered the cranial cavity through the nose, as for instance meningococci? There are cases of the mild or abortive type of meningococcic meningitis in which I believe recovery may occur without serum therapy but by lumbar puncture only. Merritt and Fremont-Smith (The Cerebrospinal Fluid, Philadelphia and London, W. D. Saunders Company, 1937, p. 97) mentioned a case of meningococcic meningitis in which recovery occurred without any therapy except lumbar puncture. In the Philippines meningococcic meningitis is a comparatively uncommon disease and does not occur in epidemics.

A. S. FERNANDO, M.D., Manila, P. I.

ANSWER.—This patient suffered a severe head trauma, sufficient to render him unconscious, leaving in its train a hemiparesis and as an after-effect a muscular weakness in the left lower extremity. Eight months later a chronic purulent otitis media and meningeal symptoms developed: nuchal rigidity, high temperature and increased otorrhea. All of these also ran their course, with recovery taking place but leaving behind the same weakness in the left lower extremity. The diagnosis of a purulent meningitis can hardly be substantiated from the data submitted. Neither does the case history present any significant data on which to establish a diagnosis of meningococcic meningitis. The sequence of events that transpired may be reconstructed from the data given: From the trauma which this patient suffered there was formed a small blood clot which, by locally exerted pressure, accounted for the hemiparesis and the muscular weakness that remained afterward. Eight months later this encapsulated, partly organized clot became infected with the same organism which produced the purulent chronic otitis media. Thus there was formed an encapsulated brain abscess which conceivably "leaked" into the tympanic cavity and partly emptied itself in the discharge from the tympanic cavity through the perforation in the drumhead. The reactions noted in the cerebrospinal fluid are strongly suggestive of a meningeal tissue reaction, which is generally termed "meningitis sympathica." The second spinal tap, taken May 18, already shows a return of the carbohydrate content of the fluid, and the succeeding taps show this element increasing. Likewise the spinal fluid chlorides increased with succeeding spinal taps. This and the successive drop in the cell content are evidence enough of a meningeal tissue reaction which was in process of recession. The absence of bacteria in the fluid is further evidence of its nonpurulent nature. This observation of an abacterial fluid precludes the diagnosis of meningococcic meningitis as well as that of an otogenic streptococcic meningitis.

The case does not assume any of the aspects of a purulent meningitis of otitic origin. It more nearly approximates that of a meningeal irritation due to a secondarily infected blood clot, the latter produced by trauma. The brain abscess may be small. At present, from the description given in the inquiry, there is no sure evidence at hand to warrant the belief that the clinical course of this lesion has completely run its course. There may be subsequent developments which will require observation by both otologists and neurosurgeons.

CHRONIC DERMATITIS

To the Editor:—A white man, aged 43, complains of severe itching of the face. Burning and scaling occur daily regardless of the season but are more severe during hot weather. His present complaint dates back to 1924, when he was working in a gold mine in Idaho and noticed a rash on his forehead, which was treated as a sweat band rash with picric ointment. This condition was followed by a severe rash over the entire face; it was of the weeping type with slabs of yellowish matter peeling off and leaving raw, oozing surfaces. He was hospitalized and advised to have his teeth and tonsils removed. Following this he was sent to the Veterans' hospital. He remained there seven months, during which time multiple boils and abscesses developed. A culture was made and vaccine used to treat this condition. There is no history of syphilis and his past history is good. I have given him a series of Lederle's special pollen antigen and a course of autohemotherapy for possible allergic reaction to wild weeds. Can you advise any further treatment to alleviate this man's condition?

M.D., Nevada.

ANSWER.—Careful search for the etiologic basis in such cases is often without avail. Multiple sensitization following the severe picric acid dermatitis with infection seems likely and a neurodermatitis may have been added during the fourteen years of suffering. The summer exacerbations may be due to a reaction to some pollen present in the air, to increased perspiration or to untoward activity of the cholinergic side of the vegetative nervous system. Low diastolic blood pressure, high metabolic rate, rapid pulse and a tendency to flush and to sweat on slight provocation would bear out the latter suspicion. A thorough general examination, if not already made, should be done with special attention to the possibility of other foci

of infection in the gastrointestinal or genito-urinary tracts. The blood picture should be studied. Possible sources of reflex irritation should be sought.

Patch tests should be made on the skin adjacent to the area of inflammation with all substances that come in contact with the patient's face or that can be carried there by the hands. A small amount of the suspected substance is placed on the skin, covered by a small square of gauze fastened with tape, to avoid confusion of the reaction to the suspected substance with that so often seen to adhesive tape. If a dry substance, it can be moistened with water or better with the patient's own perspiration. No substance irritating to a normal skin should be used nor should any volatile substance be covered. The patches should be left on for two days unless severe itching occurs before that time. On removal of the patch it is well to mark the number of the patch on the skin so that a late reaction may be recognized. Inhalation tests may be made also, having the patient snuff up various dusts that are apt to contaminate the air he breathes and noting any exacerbation of the dermatitis that may follow. All positive tests should be repeated to rule out coincidence.

Whether or not such investigation succeeds in detecting the cause or causes of the dermatitis, local treatment is important. When the skin oozes or is acutely inflamed, cool wet dressings of aluminum subacetate solution, one part to sixteen parts of water, or calamine lotion or saturated solution of boric acid should be used. As the acuteness lessens, zinc paste applied thinly may be substituted, or a dry skin may do better with zinc ointment or even borated rose water ointment. Stimulating agents such as salicylic acid, resorcinol, crude coal tar, wood tars or sulfur must be used with caution. Before applying them to the whole affected area a patch test should be made or the proposed preparation should be applied to a small part of the inflamed area, which amounts to the same thing. Only after such application has proved harmless should the preparation be used generally.

Ultraviolet rays benefit some patients in this category, used locally and generally in suberythema doses. If the patient goes outdoors he probably gets all the ultraviolet radiation that is good for him. If roentgen rays have not been used they may afford great relief for a time, though the probability of a definite cure is slight. One-fourth erythema dose, 87 roentgens once a week for a few treatments, should bring relief if the dermatitis is amenable to this agent and in any event not over three or four full doses, 1,050 or 1,400 roentgens, should be given. The patient must be warned against repetition of roentgen treatment at any future date. For this reason it is preferable to save the roentgen rays for severe exacerbations resistant to other measures.

Sedatives such as bromides or phenobarbital may be of great assistance. Every effort must be made to restrict rubbing and scratching, for if this is not stopped no effect will be obtained from other measures. Mental treatment is of great importance.

Attempts to alter the balance of the vegetative nervous mechanism by autogenous blood injections or intravenous injections of solution of sodium thiosulfate may be helpful.

#### VASOMOTOR RHINITIS

*To the Editor:*—A girl aged 19 has been suffering from vasomotor rhinitis for the past year, the onset having been last July. Treatment has consisted of nonspecific protein (orally), calcium, nitrohydrochloric acid, belladonna, ephedrine and phenobarbital without noticeable effect. Local applications of various vasoconstrictors, such as ephedrine, epinephrine, benzedrine and neosynephrin give but temporary relief. She has been tested cutaneously for foods, epidermals and pollens, also for incidentals such as dust, kapok and orris root, with no positive reactions. A competent rhinologist confirmed the diagnosis but was unable to add anything further to the treatment. Physical examination and urine and blood tests reveal no deviation from normal except for atrophic chronic infected tonsils. Can you suggest any other treatment? Would there be a possibility that tonsillectomy might improve her condition?

R. HUGH WEISEL, M.D., Bowmanstown, Pa.

*ANSWER:*—In the absence of detailed information, it is impossible to say wherein the treatment could be improved. It would be helpful to know whether the skin tests for food were done by the scratch method or by the more sensitive intradermal method, always remembering that at best the number of positive reactions may not be over 25 per cent. Those using the intramucosal method report as high as 80 per cent positive results. The antigen is injected in minute amounts in the anterior end of the inferior turbinate. Lastly, no mention has been made of the leukopenic index test following food ingestion. The term "vasomotor rhinitis" covers a multitude of conditions. It would be necessary to know whether there

are polyps present and whether these are large enough to produce mechanical blocking of the nasal passages. It would be most important to see whether there is a true hypertrophy of the turbinates and the posterior ends of the inferior turbinates, hypertrophy of which would mean at least some degree of surgical intervention before the patient could be expected to breathe well through the nose. There remain a number of therapeutic methods regarding which there is some dispute but which in individual cases have offered some measure of improvement, including zinc ionization of the nasal mucosa, the injection of alcohol solutions beneath the mucosa of the turbinates, the similar injection of sodium morrhuate solutions and the blocking of nasal nerves with alcohol as advocated by Otto J. Stein in 1908 (Some Observations on Hyperesthetic Rhinitis, *Laryngoscope* 18:692, 1908) and others since. Hansel in his textbook "Allergy of the Nose and Paranasal Sinuses," St. Louis, C. V. Mosby Company, 1936, gives complete information about the treatment of this type of disease.

#### REMOVAL OF EXCESS HAIR

*To the Editor:*—In Queries and Minor Notes (THE JOURNAL, Dec. 25, 1937, p. 2161), regarding removal of hair from about the nipples in a woman aged 25, the answer states: "Electrolysis is the only approved method for permanent removal of hair." I should like to know what are the objections to the use of the coagulating current (high frequency) for the same purpose. Should the hair about the nipples be handled in a different way from that of the face? Please discuss electrolysis (with one needle and with multiple needles) and coagulation in the permanent removal of hair.

FRANCESCO RONCHESI, M.D., Providence, R. I.

*ANSWER:*—Although both methods mentioned require experience to remove superfluous hairs properly, electrolysis with the single needle method is usually a wiser procedure, associated with less local reaction and lessened danger of scarring. To remove hairs about the breast area with electrolysis, the procedure is much the same as that for the removal of hair about the face. While theoretically, there may be increased speed with the multiple needle method of electrolysis, practically it is much more difficult to control any variation in current by this method; scarring is more likely to supervene, and there is also more associated pain with the multiple needle method. All in all, the single needle method is the expeditious one, and a careful operator can accomplish as much with fewer complications and less discomfort to the patient by this method.

#### BRAXTON HICKS CONTRACTIONS, PENTOBARBITAL SODIUM AND STILLBIRTH

*To the Editor:*—A primipara aged 32 was delivered of a 6½ pound (3 Kg.) baby. Although heart beats (130) were heard until a few minutes before delivery, it was not possible to resuscitate the baby. Labor and delivery were normal. The second stage of labor was a little long, over one and one-half hours. Four and one-half grains (0.3 Gm.) of pentobarbital sodium was given and nitrous oxide gas was used to dull the pain. There was no toxemia during pregnancy; the kidneys were normal. The blood pressure was 94 systolic, 60 diastolic. The mother had contractions of the uterus for the last four or five months of pregnancy. Sometimes they were five minutes apart but usually twenty minutes, a half hour or an hour apart, day and night. There was no pain, although the uterus became tight. Could they have weakened the baby so that it could not stand labor? Could anything have been given to stop these contractions? Twelve years ago when the mother had an appendectomy her doctor told her she had an infantile uterus. She is a doctor's wife and was anxious to have her baby. If she becomes pregnant again, would you advise a cesarean section?

M.D., Texas.

*ANSWER:*—It is difficult to surmise the cause of death of the baby in the absence of a necropsy. Many babies who appear perfectly normal on external examination have serious congenital anomalies incompatible with life. The analgesia that the patient received could likewise have contributed to the fatal termination. Although the dose of pentobarbital sodium was not excessive, this drug combined with the administration of nitrous oxide tends to increase the incidence of asphyxia in the newborn with the resultant hazard of a fatal termination.

The Braxton Hicks contractions that occurred during pregnancy could not have been responsible for any possible damage. These contractions often become severe enough at the end of pregnancy to require some sedation and yet produce no harmful effects. It is hardly possible that they could have weakened the baby. Although progestin has been recommended for the relief of these contractions, its use would not have been indicated in this case. An infantile uterus likewise would not be a contributory cause. It is possible that such a condition would be a cause for sterility, but this patient had an uneventful pregnancy and labor.

If the patient becomes pregnant again, a cesarean operation need not be considered because of this recent experience. Her pelvis must be quite adequate, and this first labor was not at all abnormal in character. It would be well, however, to use analgesic drugs sparingly and perhaps substitute some drug for the pentobarbital sodium. It is unlikely that this unfortunate experience would repeat itself.

#### CARDIORENAL HYPERTENSION AND APOPLEXY

*To the Editor:*—A patient aged 56, 5 feet 5 inches (165 cm.) tall and weighing 185 pounds (84 Kg.), has suffered from hypertension of nephritic origin for the last ten years. He had a "stroke" Aug. 14, 1938, the right leg, right arm, the right side of the face and speech being involved. August 16 his right leg improved and he could raise his arm, but on August 17 he had another hemorrhage, the leg becoming bad again, the arm the same, and the speech became more "thick" and indistinct. He again showed improvement August 20 but developed an annoying hiccup August 22. At first I controlled it with an ice bag. Later on that was not enough. I tried sedation, belladonna, bromides and hyoscyamus, which did not help, so then I tried atropine. This controlled it, but when I paralyzed the vagus and controlled the diaphragm I lost control of the heart, and the pulse went up from 75 to 105. What would you advise me to do in this case? What is the prognosis?

HARRY HALLARMAN, M.D., New York.

**ANSWER.**—Hypertension with renal involvement, whether secondary or not, has an ominous prognosis. The occurrence of apoplexy implies, but does not prove, that there is considerable arterial degeneration. It is impossible to foretell whether renal decompensation, cardiac decompensation or another cerebral accident will terminate this man's life.

The management of his tachycardia can be guided only by data which are not available. With the acceleration of pulse following vagal paralysis there may have been changes in the arterial tension which would modify the suggestions. If his pulse does not become more rapid it might be wise to do nothing about it, for the time being at least. Attention to the renal aspects of the situation is of the utmost importance; particularly efforts should be continued to maintain the hemoglobin concentration of the blood at as high a level as possible. With the extensive paralysis the patient is of necessity quiet. Although he is grossly overweight, there is hardly justification in expecting weight reduction to accomplish anything. An adequate supply of dextrose for the myocardium is vitally necessary. Digitalis can be used if its effects are carefully watched; it does not cause an increase in the arterial tension. However, there is no evidence in the query that the relative tachycardia is a sign of myocardial exhaustion. Oxygen inhalation would tend to slow the pulse, but unless the situation gets acutely worse the present pulse of 105 hardly warrants its continuous administration.

#### LIGHTNING CLEANER

*To the Editor:*—An industrial cleansing fluid sold under the name of Lightning Cleansing Fluid, distributed by the Mortemoth Company, Milwaukee, has been causing rather distressing symptoms of nausea, epigastric pain, vertigo and drowsiness. I should appreciate a report of its contents with a statement as to its organic effects, temporary or permanent, if any.

M.D., North Carolina.

**ANSWER.**—The Mortemoth Company appears to manufacture or distribute a variety of cleaning agents, fumigants and insecticides. The product mentioned apparently is "Lightning Cleaner" for use in fur and lining cleaning. This product is referred to in promotional literature as "a balanced combination of cleaning solvents especially prepared for the fur trade." Further it is described as nonexplosive and without fire risk. Without knowing the exact composition it is inferred from the statement as to nonflammability that this cleaner contains one or more chlorinated hydrocarbons. Carbon tetrachloride is typical of the chlorinated hydrocarbons found in this type of cleaning agent. Manifestations mentioned in the query are somewhat characteristic of the action of chlorinated hydrocarbons. The symptoms suggest only comparatively minor injury but some chlorinated hydrocarbons are capable of producing direful and acute manifestations centering about damage to the liver. The clinical manifestations and associated pathologic changes are similar to those of acute chloroform poisoning—chloroform itself being a chlorinated hydrocarbon. No chronic form of the disease is known but persistent sequels from acute poisoning may arise. In view of the limited information furnished in the query and in view of the lack of precise analysis of the product in question, no definite stand can be taken as to either diagnosis or preventive measures, but the entire situation suggests an injurious action from chlorinated hydrocarbons calling for prompt preventive steps.

#### POSSIBLE NEUROSYPHILIS: TREATMENT

*To the Editor:*—In May 1937 a baker complained of insomnia, lack of ambition, numbness of the hands and feet (the latter especially if sitting still for some time or at night), sour eructation, not especially at meals, and belching gas. He also had an occasional dizzy spell after standing up. He has had these symptoms for several months. He had supra-orbital headaches for three weeks. One year earlier he had typhoid injections followed by sudden diplopia and internal squint of the left eye. In March 1937 an optometrist who examined his eyes told him that no improvement could be made in his lenses and that there must be some general toxic condition causing his double vision. The diplopia is worse in the evening after he becomes tired. The optic nerve and fundus are apparently normal. In 1933 he had ulcers of the mouth and tongue; in May 1936 all his teeth were removed because of abscesses and pyorrhea. He does not remember having any sores. His wife died in 1930 at 32 of myocardial failure and possibly hypertension. She has had two children, now 7 and 8 years old, whose blood tests are negative. There have been no miscarriages. The patient has slight receptive deafness of the left ear; his hearing has been defective for twenty years. He had carbuncles in 1928. Physical examination showed a blood pressure of 125 systolic and 95 diastolic. There were no other abnormalities in the heart, lungs or abdomen except that there was a slight general alopecia, the pupils do not react to light, and the right pupil is slightly irregular in contour and slightly larger than the left. He has had a thick yellow postnasal discharge for five years. The knee jerks are normal, equal bilaterally; there is no Romberg sign and no tremor. The Wassermann and Kahn reactions were 4 plus. Since the beginning of treatment he has had three courses of twelve injections each of 0.6 Gm. of neoarsphenamine alternating with injections of three courses of 1 cc. of bismuth subsalicylate. The first course of bismuth consisted of seven injections of 1 cc. (2 grains). The second course consisted of twenty-four and the third of fourteen injections. The bismuth subsalicylate was alternated with neoarsphenamine in continuous treatment. He has also had potassium iodide continuously since May 1937: 15 grains (1 Gm.) daily up to a few months ago, when it was increased to 24 grains (1.5 Gm.) daily. Under this treatment the double vision improved slightly. He still has a moderate amount of internal squint of the left eye, but the knee jerks are 4 plus and equal; there is no Romberg sign. The finger to nose test is negative. May 18, 1938, the blood Wassermann reaction was 3 plus, the Kahn reaction 4 plus. The first spinal fluid examination was made June 26. The colloidal gold reading was 0000000000, the Wassermann reaction 2 plus, Pandy's test questionable. There was no apparent increase in pressure, the fluid was clear in color and it contained one white blood cell per cubic millimeter. The patient is somewhat nervous and irritable; however, he has a steady gait and a clear mind and his memory is normal. 1. What further treatment is indicated? Has the patient neurosyphilis? 2. Does the colloidal gold or the globulin test or the positive spinal Wassermann reaction determine the presence of neurosyphilis? 3. Is trypanamide or mapharsen indicated here? 4. Is the patient considered Wassermann fast? If so, is Wassermann fastness of any significance? 5. How long do you believe this patient has had syphilis? Where are the lesions of syphilis in this case?

M.D., Connecticut.

**ANSWER.**—These questions are of the type that cannot be answered by yes or no, as some of them include problems of syphilology that require considerable discussion. Neither are the data given with regard to the patient sufficient to make the answers conclusive.

1. The patient has been given in a little over a year thirty-six injections of neoarsphenamine and forty-five injections of a bismuth compound and some potassium iodide, apparently followed by definite improvement. However, as some of the symptoms have persisted, it would seem advisable to continue the treatment with at least two more courses of neoarsphenamine and at least four more courses of a bismuth compound. Even though the spinal fluid examination is not conclusively positive, the diagnosis of neurosyphilis seems justifiable in view of the other manifestations. The spinal fluid was examined apparently after considerable treatment had been given, which fact may explain the type of spinal fluid report obtained. If the fluid had been examined before treatment was started, the report might have been strongly positive. The clinical signs are suggestive of neurosyphilis of the meningovascular type.

2. A spinal fluid examination to be adequate should consist of the following tests: a cell count done immediately at the time of the withdrawal of the fluid; a flocculation or precipitation test; a colloidal gold test; globulin, protein and sugar estimations, and a pressure reading. The cell count is the most significant single test done on the fluid in the examination for syphilis, with the serologic test and the colloidal gold test following in that order. The degree of positivity of the various tests creates the picture of the positive spinal fluid as being of mild, moderate or severe degrees of positivity. One spinal fluid examination, however, does not warrant deduction as to the degree of neurologic involvement in a given case. It is only by repeated spinal fluid examinations that the severity of the spinal fluid involvement can be accepted as authentic. For example, the typically parietic type of fluid in a patient who has mild or early signs of neurosyphilis does not mean that the patient has dementia paralytica or that later on he will develop it. The same idea is applicable to a negative spinal fluid in the

presence of suggestive clinical symptoms of neurosyphilis. Further treatment, with observations of the patient and several more spinal fluid examinations, are usually necessary to settle such an issue conclusively.

The presence of a positive globulin test with all other tests of the spinal fluid negative is of no significance. Similarly, a colloidal gold curve of the syphilitic or parietic type is of no diagnostic significance if all the other factors are normal. In brief, it is the ensemble of the degree of positivity or negativity of the tests that creates the picture of a negative or positive report.

3. Tryparsamide might be used to advantage in this case if examination of the eyegrounds shows no abnormalities. If tryparsamide is used it should be given in series of ten injections with a similar amount of a bismuth compound given concurrently. There should be a rest period of two months between courses. Mapharsen would probably not be any more effective than the other arsphenamines.

4. It is too early to determine whether this patient is "Wassermann fast," and the question as to whether he has neurosyphilis must be settled before the patient can be classified as "Wassermann fast." If the serologic reaction of the blood remains positive in a patient who has neurosyphilis, the use of the term "Wassermann fast" is not justifiable because the involvement of the nervous system is the explanation for the persistence of the positive serologic reactions of the blood. The term "Wassermann fast" is limited to those patients who have no clinical evidence of visceral or neurologic syphilis and who have a negative spinal fluid. It is a better practice to think in terms of the status of the syphilis rather than in terms of the status of the serologic reaction, because not infrequently a so-called Wassermann fast patient is in the process of developing manifestations of syphilis that will become clinically obvious if he is observed long enough. On the other hand, the occasional patient is encountered who will maintain a positive blood reaction for many years and never show clinical evidence of late manifestations of the disease.

5. It is impossible to guess the duration of the syphilis. The inference from the data submitted is that if this patient has neurosyphilis it is of the meningovascular type with the vascular involvement predominating.

#### LABYRINTHINE VERTIGO

*To the Editor:*—A white man aged 61 has had vertigo for the last two years. He has had three attacks lasting about a week. Ordinarily he is active and works hard but during these episodes of vertigo he is utterly incapacitated for at least a week. There is no syncope, scotoma or tinnitus. He says that it is usually on changing position, on arising in the morning particularly, that he experiences the most discomfort. His present attack is associated only with vertigo but his last attack a year ago was marked also by a violent headache, which he described as a "tightening and pulling sensation on the back of his head and neck." He had gonorrhea thirty years ago and some chronic gastrointestinal complaints, which were corrected by attention to diet and bowel hygiene. His appetite is good; he drinks a small cup of coffee and a glass of wine occasionally but uses no tobacco. He is well developed and well nourished, weighs 170 pounds (77 Kg.) and is 6 feet (183 cm.) tall. The eyes, ears and throat are normal. Some nasal obstruction is present as the result of a poorly performed submucous resection many years ago. The lung fields are clear. The heart is slightly enlarged to the left (0.5 cm.) and there is a transient systolic blow heard at the apex, which is not transmitted. His blood pressure has never been higher than 113 systolic. The diastolic pressure varies between 60 and 70. During the last seizure his blood pressure dropped to 96 systolic and 58 diastolic. The peripheral vessels are definitely sclerosed. The pulse is 60, hard, full and regular. Enlargement of the abdominal viscera is absent. The lower extremities are normal except for some varicosities. Two years ago at the onset of the illness the patient was seen by an internist, who had a complete work-up done on him. He was also seen by an ophthalmologist, an otolaryngologist and a neurologist. The results of these examinations were pooled and a diagnosis of arteriosclerosis of the labyrinthine vessels was made. He was placed on a diet, wine and coffee were forbidden, and iodides were given orally. At the time blood Wassermann, blood count, chemistry urinalysis and electrocardiogram were all negative. What other phases of this man's illness should be investigated? What else ought to be excluded? What form of therapy is best applicable? What is the opinion with regard to the use of strychnine, ephedrine and thyroid preparations in a case such as this? How long should the regimen be kept up if instituted?

M.D., Brooklyn.

*ANSWER.*—The symptom as described is suggestive of some labyrinthine irritation of one or both labyrinths. Its rotational character and its aggravation by sudden movements of the head would also point to the same cause. If the eyes were observed during the attacks, a mild rotatory nystagmus might be noticed. The unusually low blood pressure as well as the drop in the latter to 96 systolic during the attacks would also point to a circulatory disturbance in the labyrinths.

The statement that the otolaryngologist's report was negative does not indicate the type of examination done which proved to be negative. For instance, an audiometric reading of both ears which may show loss of hearing in the high pitch register, combined with a reduction in responses to the caloric test of the vestibular apparatus from the vertical canals (with the head in the upright position), may point still further to circulatory involvement in the labyrinth. The vestibular tests should be done in all cases of vertigo, as occasionally a perverted response may point to possible intracranial disturbance.

The observations in this patient, however, seem to point to a Ménière syndrome due to circulatory disturbance. Foci of infection such as the teeth and tonsils should definitely be eliminated.

Treatment should be directed toward keeping the blood pressure at a higher level. The drugs mentioned do not seem to possess any specific action for vertigo. If the attacks become more frequent, the Furstenberg regimen should also be instituted: elimination of sodium chloride from the diet and the administration of large doses of ammonium chloride 3 Gm. (45 grains) in six capsules with each meal three times a day. This is given for three days and skipped for two days. If relief is obtained this regimen may be carried on indefinitely.

#### ACRODYNIA OR INFECTION?

*To the Editor:*—A white boy aged 9, 4 feet 4 inches (132 cm.) tall, weighing 75 pounds (34 Kg.) is pale and thin. He had no definite area of discomfort but looked acutely ill. The temperature was 102.2 F., the pulse rate 110 to 120. Physical examination showed definite photophobia, normal eyesight, the inferior palpebral conjunctivae slightly injected on both sides. The ears, mouth and pharynx were normal. The tonsils were out. The lungs were clear and normal. There was tachycardia; no murmurs were present. The abdomen was soft, the spleen not palpable. There were no tender areas on the abdominal wall. The kidneys were negative to palpation. The skin was moist and pale. The hair was of light color. Neurologic examination showed no nystagmus; the abdominal reflexes were present. There were no pathologic reflexes and no tremor. There was active sweating. Blood pressure was 120 systolic, 70 diastolic. The patient's history included measles, chickenpox, pertussis, mumps, grip and allergy to several foods. The mother tells of the complaints of headache, fatigue, anorexia and pains in the leg muscles, which started a week before my visit and were mildly present during visit. The patient perspires chiefly during the day, even when at rest; he has no night sweats. The temperature has been above normal for a week, often going to 101 and 102. There is no trouble with breathing except during epistaxis and there is no history of cough or dyspnea during this illness. The patient has a tendency to scratch himself, but no exanthems or cutaneous blemish has been noted. The patient is bright in school but shy of playmates. He literally "wants to be alone"; he sleeps a lot and is relatively inactive for a boy of his age and weight. His constant companion is his radio, which he keeps at a low pitch. He likes a darkened room and quiet. His first urine examination showed 1 plus albumin, some white blood cells, phosphate crystals and some bacteria. Another specimen of urine two days later was negative except for some hyaline casts. Later specimens of urine were negative. The hemoglobin is 80 per cent (Sahli), red blood cell count 3,700,000, white blood cells 9,100, neutrophils 68 per cent, eosinophils 1 per cent, lymphocytes 24 per cent, mononuclears 5 per cent, myelocytes 2 per cent. The Wassermann and Kahn reactions were negative. Tuberculin tests were negative (intracutaneous method). The child was treated for eight days, during which time his temperature and pulse came down to normal and he became active. Follow-up was uneventful. The therapy was alcohol sponge baths for excessive temperature; ammonium mandelate 5 grains (0.3 Gm.) every three hours by mouth for urine disinfection. Cod liver oil and brewers' yeast tablets were given in large quantities. Fluids were forced during the days with high temperature. Later a high caloric soft diet was given. Was this just a mild infection of the genito-urinary system (probably pyelitis) or the not too well known Swift-Feer disease? What would be the latest therapy of the latter?

ROBERT SCHWARTZ, M.D., Jamaica, N. Y.

*ANSWER.*—Most cases of Swift-Feer disease, or acrodynia, occur between the ages of 6 months and 3 years, rarely after 6 years of age. The common symptoms of acrodynia are insidious onset, listlessness and apathy or irritability and restlessness. The child will no longer play or smile. The appetite is poor. There is little if any fever unless intercurrent infections develop. The hands and feet are pink or cyanotic, the changes being more marked in the fingers and shading off gradually toward the wrist; pain, itching and burning occur to a marked degree in them. Transitory rashes appear on the trunk and extremities which may resemble urticaria, measles or scarlet fever. The disease lasts for several months. Excessive perspiration is marked and macerates the skin. Desquamation of the palms and soles occurs at frequent intervals. The child is a picture of abject misery. Photophobia is usually present. There is definite weakness of the musculature. The systolic pressure rises even in small children to from 120 to 150. The pulse is fast. The deciduous teeth frequently fall out. Insomnia and

constant tossing about and rubbing of the hands and feet are present. Maniacal symptoms may occur. As the disease progresses, the patellar reflexes are lost.

Regarding treatment there is nothing specific, as the etiology is unknown. Large doses of sedatives are necessary to control the extreme restlessness, pain and insomnia. Soothing lotions are used on the skin. Atropine in large doses lessens the excessive perspiration. Frequent baths and proper mouth hygiene are necessary. The diet must be forced because of the severe anorexia, even gavage feeding occasionally being necessary. A high vitamin diet is indicated, particularly in vitamin B complex and D and liver. Some have advocated ultraviolet rays. Patients should be kept out of hospitals because of the great danger of intercurrent infections.

It would seem that the patient described did not have acrodynia because too many of the classic symptoms were absent. He apparently did not have pyuria, as this is rare in a boy of this age and the one pathologic urine might be found in any febrile condition. In febrile pyuria (pyelitis) the fever subsides some days before the urine clears up, which was the opposite in this case.

The symptom complex described could have been an ordinary grippal infection even without obvious respiratory involvement, or a mild typhoid or paratyphoid infection even without enlargement of the spleen, or even a mild rheumatic fever even without a heart murmur, or a rarer condition such as malaria or undulant fever.

#### ANGINA PECTORIS OR ANXIETY NEUROSIS

*To the Editor.*—A white man aged 38 complains of intermittent precordial pain and oppression radiating down the left arm and up the left side of the neck. He also complains of fatigue, lassitude and "lack of pep" and states that late in the afternoon and early in the evening he becomes sleepy. This has been going on with remissions for the last three years. Physical or mental activity do not seem to influence these complaints much. He is a WPA engineer and his duties require him to drive about 110 miles several times a week. His wife has an arrested case of pulmonary tuberculosis. He has three children alive and well. He uses tobacco in the form of cigars in moderation and alcoholic beverages in periodic sprints, although he states that at present he takes a cocktail only occasionally. He had "nervous breakdowns" at 15 and 24 and says that nervousness seems to run in his family. His appetite is usually good, although he has had some gastrointestinal distress, such as gas, bloating and occasional heartburn. He weighs 200 pounds (91 Kg.) and is 5 feet 11 inches (180 cm.) tall. His weight has come down 4 pounds (1.8 Kg.) in the last month (I have put him on a 1,200 calory reduction diet). His blood pressure has ranged from 160/102 to 130/88. The rest of the examination is essentially negative except for the heart, which shows a slight enlargement to the left and downward and also a moderate accentuation of the second aortic sound. There are no murmurs; the pulse rate is 82 per minute and is regular. The Kahn reaction of the blood is negative, as is urinalysis. A basal metabolism test taken recently was plus 13 per cent. The fasting blood sugar is 90. My impression was that of a mild or perhaps pseudo-angina, with a possible hyperthyroid condition, mild hypertension, obesity and psychoneurosis. I have had him on theophylline with ethylenediamine, 1½ grains (0.1 Gm.) three times a day after meals, elixir of phenobarbital 1 drachm (4 cc.) three times a day; glyceryl trinitrate 1/100 grain (0.00065 Gm.) if necessary, and his reduction diet. He has been on this regimen a little over a month with no apparent improvement in his complaints. He has considerable financial worries and now is worrying about his physical condition despite my assurances that he will probably outlive me. I have hesitated to use benzedrine sulfate tablets for his extreme lassitude because of his anginal symptoms and mild hypertension. Cessation of the phenobarbital does not improve this troublesome complaint. I would appreciate any suggestions you can give me as to diagnosis and treatment.

M.D., West Virginia.

*ANSWER.*—One cannot lightly dismiss the probability of angina pectoris. Unfortunately there is no positive method for proving or disproving such diagnosis. There are certain points in the history which throw some doubt on this diagnosis. The fact that the distress is uninfluenced by physical or emotional strain does not fall in line with angina pectoris. Anginal pain is far more often substernal than precordial. The failure of glyceryl trinitrate to give relief interposes another obstacle to a definite diagnosis of angina pectoris.

The hypertension plus a moderate cardiac enlargement justify a diagnosis of mild hypertensive disease, but a basal metabolic rate of only plus 13 per cent without tachycardia and with obesity and somnolence does not offer secure ground for a diagnosis of hyperthyroidism.

If one were to disregard the pain, it seems that a diagnosis of psychoneurosis, probably an anxiety neurosis, with mild hypertension would be quite justified. Indeed, the pain may be a part of the psychoneurosis. The background of nervousness adds weight to such an assumption.

It would seem logical to manage this case as an anxiety neurosis, at the same time guarding against anything that would be detrimental to angina pectoris.

The use of theophylline with ethylenediamine or one of the other purine base compounds should be continued because of its probable beneficial effect on the hypertensive heart disease, since compounds of this nature exert a mild diuretic and cardiac stimulating action. The general management of anxiety neurosis may be found in any good textbook dealing with the subject.

#### HIRSUTISM IN YOUNG WOMAN

*To the Editor.*—A woman aged 25 had a supravaginal hysterectomy two and one half years ago for chronic metritis and endometritis with menorrhagia, metrorrhagia and secondary anemia. The artificial menopause thus induced has been attended with some of the milder endocrine manifestations, but her general health has been good. In recent months she has noticed an increasing hypertrichosis or hirsutism, which is becoming conspicuous on the face and soon may interfere with her occupation as saleswoman. What is the latest knowledge about the arrest or correction of this condition? It is my impression that endocrine imbalance incident to the operation may be causative. In *THE JOURNAL*, Jan. 1, 1938, page 84, an abstract from the *Münchener medizinische Wochenschrift* reports the efficacy of an ointment containing estrogen in the treatment of ovarian dermatoses. Have you any report of the use of such a preparation in hypertrichosis in the female?

M.D., California.

*ANSWER.*—The inquirer speaks of this as an artificial menopause. If the operation was only a supravaginal hysterectomy, the woman does not have an artificial menopause but only cessation of menstruation as the result of removal of the uterus and its endometrium. To produce an artificial menopause, both ovaries must be removed or their function must be destroyed by x-rays, interference with their blood supply or other means.

The development of hypertrichosis or hirsutism on the face is a separate condition and bears no relation to the supravaginal hysterectomy except possibly indirectly. It is possible that the excessive preoperative uterine bleeding which this woman experienced and her hirsutism could have been influenced by a like cause; viz., disturbance of the adrenal cortex.

The excessive bleeding may have been due to a chronic pelvic inflammation or to a uterine fibroid. If these conditions are ruled out, one must consider the possibility of disturbance of any one or any combination of the four endocrine factors which are responsible for the normal menstrual cycle; viz., the follicle stimulating and the luteinizing hormones of the anterior pituitary and the estrogenic and luteal hormones of the ovary.

There are at least four endocrine conditions that may be responsible for masculinization of the female, of which hirsutism may be a prominent feature. The first of these is an adrenal cortex tumor or hyperplasia with consequent hyperfunction. Reichstein (*Helvet. chim. acta*, 19:223, 1936) isolated an androgenic hormone from the adrenal glands that stimulates the masculine characteristics in the male and masculinizes the female. He named this adrenosterone. Removal of cortical tumors in women have been followed by reversion to normal.

The second condition in which hirsutism may be an accompanying sign is pituitary basophilism. This condition is almost always associated with disturbance of the adrenal cortex, but the two syndromes differ sufficiently to indicate that while they may be related they are not identical.

The third condition that may produce hirsutism is an arrhenoblastoma of the ovary which contains male testicular tissue.

The fourth source of hirsutism may be a heterosexual gonadal rest in the parovarian gland, which, with the decline of the primary gonadal function, may take on fresh activity in the direction of the opposite sex. This is more apt to occur at the menopause.

It should not be difficult to rule out pituitary basophilism. An arrhenoblastoma should produce some evidences of masculinization, such as enlargement of the clitoris, masculine type hair growth and amenorrhea. Menstruation is excluded in this case since the operation, but because of the fact that this girl had excessive uterine bleeding it militates against a diagnosis of arrhenoblastoma. Hirsutism produced by reactivation of masculine rests in the parovarian gland usually occurs at the menopause and not in young women and again should be associated with amenorrhea.

The most probable diagnosis in this case is tumor, hyperplasia or hyperfunction of the adrenal cortex. A moderate degree of hirsutism in women is not uncommon. There are many young women who have heavy, coarse hair on their legs and forearms which they shave, a moderate hair growth on the lower part of the abdomen to the umbilicus and some on the upper lip and chin over the zygomatic arches. However, if the condition is pronounced, the adrenal glands may be visualized by roentgenograms made after injection of air into

the perineal fascial space. This procedure is of doubtful value unless a fairly large tumor is present, and it may be accompanied by sudden and alarming complications. Bilateral exploration of the adrenals through incisions in the upper posterolateral lumbar regions can be done, but this is a serious operation when no definite evidence is at hand.

There is no endocrine treatment available, for in these instances there is probably a hyperfunction to treat and unless the tumor, if present, or the offending gland can be partially removed, there is not much hope for success.

#### WHEAT GERM OIL IN THREATENED ABORTION

*To the Editor:*—I am anxious to give the wheat germ oil treatment for threatened abortions a fair trial, but on account of the expense of adequate doses many of my patients cannot afford it, and if it must be fresh and kept cold I often wonder whether my patients get a potent product when they do buy it. Can you outline a diet for pregnant women to use during the entire pregnancy so that they will not need any of this extra vitamin? What about wheat germ that is sold at the health counters?

C. E. CASWELL, M.D., Wichita, Kan.

*ANSWER:*—The use of wheat germ oil in the treatment of women who have repeated abortions has found favor with some clinicians. There is now considerable evidence to indicate that the addition of vitamin E is beneficial to some of these patients. There is less evidence as to the value of treating threatened abortions with vitamin E. Usually if symptoms of threatened abortion manifest themselves, particularly bleeding, pathologic changes have already taken place in the ovum or in the chorionic vesicle incompatible with the continuation of the normal gestation. The addition of vitamin E to the diet, therefore, should be instituted early in the pregnancy in cases of habitual abortion and can be continued to viability of the fetus. Wheat germ oil should be kept cold to prevent deterioration. Green foods, such as lettuce and watercress, milk and milk products, are rich sources of vitamin E. It has been suggested, however, that some individuals have difficulty in assimilating a sufficient amount of this substance from their diets so that additional vitamin E is advisable. The Council on Pharmacy and Chemistry has not accepted any claims for vitamin E for this or any other purpose.

#### PSEUDOHERMAPHRODISM

*To the Editor:*—I delivered a pseudohermaphrodite on March 14, 1938. The child is the ninth baby of American parents, the father being a lease worker in the oil field. Both parents are of average intelligence and the other eight children are all living and perfectly normal. The pregnancy was uneventful and delivery was accomplished easily and normally eight hours after onset and without laceration. The birth weight was 7 3/4 pounds (3,515 Gm.). The child is perfectly normal in every way except as to the genitals: On either side of the midline, occupying the site of the labia majora, is an area of wrinkled and creased scrotal skin, somewhat pouched, each containing a movable mass the size of an olive seed. These two areas merge over the pubic site, forming an inverted U shaped arrangement. Emerging from the lower curve or the inner curve of the U is a structure which a casual glance would call a penis. It is considerably larger than the normal penis of a newborn baby with well developed glans, about one third of which was covered with prepuce. A small meatal dent appears at the normal site of a penile meatus, but there is no urethra-like passage in the structure. This fact, with the small amount of prepuce, identifies the structure as a clitoris. It further occupies the site of the normally placed clitoris, being below the mons and where the anterior ends of the labia minora would join if they were present. The dark area lying posterior to the cliteropenile structure is covered only with mucosa and is so fragile that the merest touch will cause bleeding. It is kept constantly protected with petrolatum gauze. It looks as though a vagina had been completely turned inside out. Through a canal the urine comes freely. A fold of the mucosa-covered tissue conceals a sphincterless anal opening. Considering these two openings as opposite angles of a rectangle, the two remaining angles mark blind passages. The one opposite the anal opening, posteriorly, is about 1 inch deep and would receive the eraser end of a lead pencil. The anterior one is smaller both in depth and in diameter. About twenty physicians in the surrounding country have seen the child, and the consensus seems to be that we must await the adolescent development of sex and genital characteristics before even a tentative decision as to sex can be made. This being the case, how shall the child be denominated during that interim—Jim or Jemima? More important just now, however, is what can and should be done to cover and protect the skinless area, which is of considerable extent.

M.D., Pennsylvania.

*ANSWER:*—The description undoubtedly justifies the diagnosis of masculine external pseudohermaphrodisism as evidenced by the presence of a rudimentary vagina, transformation of labia majora into scrotal-like structures in which a mass, presumably testes, is palpable, and an elongated penis-like clitoris. Management of this case should largely depend on whether or not internal female sex organs are present. No mention has been made of whether or not a rectal examination reveals the presence of

internal female sex organs. If rectal examination is unsatisfactory, a pneumoperitoneum may be necessary to establish the presence of such organs. Finally, laparotomy may be justified as a final diagnostic measure. If the presence of ovaries is established, removal of both testes and plastic restoration of the vagina would be indicated. In this way a definite female tendency would be established. If no ovaries are to be found, it would seem wiser to leave the testes in situ and thus establish a definite male tendency. Operative details may be found in Hugh Young's book on pseudohermaphrodisism.

If no operation was performed, the possible presence of both male and female generative organs doubtless would lead to the pitiful picture of the fully developed intersex, combining both male and female secondary sex characteristics. Much consideration should be given to the time to be chosen for the operation. There is no doubt that a prepubertal operation would give much better chances as to final sexual development. The presence of functioning opposite gonads would definitely suppress such development.

As it seems desirable to establish a definite sex before onset of school age, an operation just before that time would seem desirable. At that time anatomic development is far enough along to establish a better diagnosis and facilitates delicate plastic surgery.

If, however, what appears to be a prolapsed vagina should give rise to inflammatory or other complications, surgical procedure at a much earlier date would be justified.

#### BLOOD IODINE DETERMINATIONS

*To the Editor:*—I am interested in instituting blood iodine determinations in connection with thyroid work. What method of procedure is most suitable to the needs of a relatively small diagnostic laboratory? It has been my understanding that most of the procedures now in use do not meet this specification, being both expensive and exceedingly complicated.

J. M. FEDER, M.D., Anderson, S. C.

*ANSWER:*—The determination of the content of iodine in the blood can now be performed in the clinical laboratory. A certain amount of practice and experience is necessary, however, before the results obtained can be used for clinical diagnosis. A clinical method, the result of ten years of hospital experience, has recently been reported (Matthews, N. L.; Curtis, G. M., and Brode, W. R.: Determination of Iodine in Biological Materials, *Indust. & Engin. Chem., Anal. Ed.* 10:612 [Oct. 15] 1938) which requires about three hours to make half a dozen blood iodine analyses. The special apparatus required costs about \$50 but it can be made by a good glass blower. The reagents are such that a single analysis costs about 12.5 cents. While it is true that in the past these methods have been expensive and quite complicated, this newer method is simpler and particularly adapted to the clinical laboratory.

#### DIVISION OF ILIOFEMORAL BAND

*To the Editor:*—I should appreciate whatever references you may have concerning the technic and indication for division of the iliofemoral band. This is sometimes called the Ober operation.

G. H. WISENER, M.D., Richmond, Ind.

*ANSWER:*—Complete details of the technic and indication for division of the iliofemoral band may be found in the following three articles:

Ober, F. R.: Back Strain and Sciatica, *THE JOURNAL*, May 4, 1935, p. 1580.

Ober, F. R.: The Role of the Iliotibial Band and Fascia Lata as a Factor in the Causation of Low-Back Disabilities and Sciatica, *J. Bone & Joint Surg.* 18:105 (Jan.) 1936.

Ober, F. R.: Relation of the Fascia Lata to Conditions in the Lower Part of the Back, *THE JOURNAL*, Aug. 21, 1937, p. 554.

#### PYLORIC STENOSIS IN GIRLS

*To the Editor:*—Lately I have heard two recent graduates from different medical schools say that pyloric stenosis in children is confined to boys. Since I had in the past two girls who were diagnosed as having pyloric stenosis in a large medical clinic, I should like to know whether this is at present the accepted opinion or whether it is the opinion of an individual investigator.

M.D., Pennsylvania.

*ANSWER:*—Pyloric stenosis is not confined to boys, but 80 per cent of the cases occur in males and 20 per cent in females. Sometimes the proportion is given as three to one instead of four to one. For further information on this subject consult the following references:

Abt, I. A., editor: Pediatrics, Philadelphia, W. B. Saunders Company 3:453, 1924.

NATIONAL BOARD OF MEDICAL EXAMINERS  
SPECIAL BOARDS

Examinations of the National Board of Medical Examiners and Special Boards were published in THE JOURNAL, December 17, page 2328.

Illinois June-July Examinations

Mr. Homer J. Byrd, superintendent of registration, Illinois Department of Registration and Education, reports the written examination (graduates of foreign schools given also a practical test) held in Chicago, June 28-July 1, 1938. The examination

covered ten subjects and included 100 questions. An average of 75 per cent was required to pass. Three hundred and twelve candidates were examined, 307 of whom passed and five failed. The following schools were represented:

School	PASSED	Year Grad.	Per Cent
University of Arkansas School of Medicine.....	(1937)	81	
College of Medical Evangelists.....	(1938)	83	
Chicago Medical School.....	(1936)	81,

## Book Notices

**Nutrition and Diet Therapy: A Textbook of Dietetics.** By Fairfax T. Proudfit, Instructor in Nutrition and Diet Therapy, University of Tennessee College of Medicine, Memphis. Seventh edition. Cloth. Price, \$3. Pp. 923, with 64 illustrations. New York: Macmillan Company, 1938.

The plan of the seventh edition of this book remains the same as in previous editions. Section one has to do with normal nutrition. Section two includes a series of laboratory lessons in the preparation of foods and diets. Laboratory lesson two, for example, comprises a discussion of the composition, structure and place in the diet of the cereals, followed by a cooking demonstration. Lesson four concerns foods that are rich in energy, including the carbohydrates and fats; this chapter opens with a discussion of bread making and the use of fats in the diet, followed by a cooking demonstration, for which the students are advised to divide into two or three groups, each making biscuits or muffins. Section three takes up diet therapy. Here is a tabulation of the different kinds of routine hospital diets—liquid diets, soft diet, light, regular, high-residue diet, bland, smooth residue diet, low residue diet, no residue, high calory diets, low protein diets, high fat diets, and so on. These chapters pertain to diets for use in different diseases: diet in pneumonia and other fevers, diet in disturbances of the stomach, diet in constipation, in liver and gallbladder disturbances, in cutaneous and allergic diseases, in diabetes mellitus, in Addison's disease, in obesity, in pernicious anemia, in kidney diseases, in epilepsy, in arthritis, in deficiency diseases and in other conditions. Here also is a table giving the normal daily dietary standards for adults with modifications to meet the needs of the body in pathologic conditions. Section four comprises recipes for different kinds of beverages, fruits, cereals, salads, soups, sauces, meats, vegetables and desserts. The appendix contains information on food values. The book has been reorganized and rewritten to follow closely the curriculum of the National League for Nursing Education. This edition presents the latest methods of teaching the fundamental principles of nutrition in health and disease; it is a valuable guide for nurses, dietitians and others interested in nutrition and diet therapy.

**Of Yesterday and Tomorrow.** By E. O. Laughlin (Eolus). Cloth. Price, \$1.50. Pp. 108. Kansas City, Mo.: Brown-White Company, 1938.

Among medical contributors to poesy, Dr. E. O. Laughlin has had a welcome in many leading periodicals and newspaper columns. He has a flair for rhythm and his medical background gives color to all his verse. This is his most recent collection. He reveals humor and humane understanding. An example of his originality is the following epigrammatic clothing of a trite concept:

### SENESCENCE

This is old age's sorrow:  
That one no more may borrow  
From Tomorrow,  
And has so many debts to pay  
To Yesterday.

**Die Technik der Operation der Gaumenspalten und Gaumenlippenspalten nebst Ergebnissen.** Von Dr. Kurt Luhmann, Oberarzt der Chirurg. Univ.-Klinik Breslau. Paper. Price, 9.60 marks. Pp. 99, with 170 illustrations. Leipzig: Johann Ambrosius Barth, 1937.

This book presents in a clear and concise way the methods of Veau and of the author for the treatment of lip and palatine clefts. The rare forms of facial clefts are not in the purpose of the book. The author believes, with Veau, that the palate must be corrected when the child is beginning to learn to speak, that is, around the second year of life. He prefers to do the lip early, between 3 and 5 months of age, profiting by the softer skeletal frame. The preferred anesthesia is, in children and adults, ether by intranasal catheter or by the drop method. Children are prepared previously with atropine and avertin with amylene hydrate. He agrees with Veau that all the necessary elements to repair the defect are present. A complete cleft and its repair with the Veau method is clearly illustrated and described. For repair of clefts of the soft and hard palate, he has abandoned the Veau method except in particular cases because he considers it inconvenient in older children; the posterior palatine pedicle is not sufficiently freed; there is a

danger of dehiscence in the zone between the soft and the hard palate provoked by excessive tension, and the soft palate lacks the necessary freedom to allow an easy and sure closure. For these reasons he proposes a method of his own, derived from the original of Langenbeck and based on layer dissection of the cleft, bilateral section of the posterior palatine pedicle, debriding lateral incisions including soft and hard palate, complete mobilization and suture by layers of the flaps. His statistics are based on 177 patients, on whom he has performed 284 operations. After the 260th, he lost two cases. In using the method proposed by Veau for the closure of the cleft palate he has had some partial failures; otherwise his personal procedure has almost always been followed by success.

**The Infant: A Handbook of Modern Treatment.** By Eric Pritchard, M.A., M.D., F.R.C.P., Consulting Physician to the Queen's Hospital for Children, London. Cloth. Price, \$6. Pp. 744, with 52 illustrations. Baltimore: William Wood & Company, 1938.

Most books on therapy, after briefly presenting symptoms and diagnosis, offer several methods suitable for the treatment of each condition described. In this book, only enough information concerning the etiology and pathology of the various diseases is given to explain the rationale on which the treatment is based. A collection of many different methods of treatment is not presented, but rather only those methods which the author has selected because he believes them to be the best and most reliable. The reader is not left any choice as to what therapeutic procedure he should adopt. The book covers the disorders of the first five years of life. The complete index will enable the reader to find quickly the information he requires. The prescriptions appended also will be found useful. The treatment methods are practical and, in most instances, clearly presented in an amply detailed manner.

**Textbook of Zoology.** By George Edwin Potter, Ph.D., Professor of Zoology, Baylor University, Waco, Texas. Cloth. Price, \$5. Pp. 915, with 455 illustrations including 15 color plates. St. Louis: C. V. Mosby Company, 1938.

Not long ago, all that was known in zoology, botany, geology and related subjects was studied under the heading of natural history. With the rapid advance in science, zoology alone has grown to such magnitude that it must be divided into numerous special fields. The number of described species of animals is said to range from 840,000 to more than a million, and one writer has said that there are probably two million species of living animals, to say nothing of the large numbers of extinct forms. The subdivision of zoology which deals with the classification of organisms according to their natural relationships is taxonomy. This textbook classifies the animal kingdom after first giving a historical review of zoology, with brief biographies and photographs of some famous zoologists. Then follows a discussion of protoplasm and many other chapters, each devoted to some one phylum or class of animals. Chapter four deals with protozoa in general, chapter six with amebas, chapter seventeen with mollusks, and so on. Insects are the most abundant creatures on the earth, comprising more than 650,000 living species, many of which have never been seen by the majority of mankind. These arthropods have been on the earth, the author says, from the Pennsylvanian times of the late paleozoic era and have for probably a hundred million years been adjusting to a changing environmental complex. Their success is evident, for in a sense the two great contending forces today are insects and man.

The author has had the cooperation of several teachers and specialists in different fields in the preparation of many of the chapters. He has made an effort to lead the student to think of biology as related to mankind and to himself. This is more evident in the later chapters of the book, which take up the mammalia, where the interesting statement is noted that the camel's blood is an exception to the rule that mammalian blood contains unnucleated, circular red corpuscles. In the chapter on animal parasitism are discussions of many specimens that are parasitic to man. The later chapters concern wild life conservation, comparative embryology, genetics, comparative physiology, paleontology, and phylogenetic relations of animal groups and the theory of evolution. The many pages of glossary seem necessary in a science that has developed so fast.

**Traité d'électroradiothérapie.** Publié sous la direction de L. Delherm et. A. Laquerrière. Secrétaire général: H. Morel-Kahn. Secrétaire adjoint: H. Elschgold. Tomes I et II. Cloth. Price, 480 francs per set. Pp. 1,081; 1109-2015, with 450 illustrations. Paris: Masson & Cie, 1938.

These two volumes stand as a monumental work reflecting the interests of the French school of electroradiology. The entire work is dedicated to Professor Arsène d'Arsonval in tribute to his contributions in the application of physical science to disease. The majority of the ninety-two separate contributors are French; others are proponents of the French school residing in other European countries or in Canada. The subject matter begins with chapters giving the history and basic physical concepts of electrophysics as they have been applied in medicine. The underlying electrobiologic and radiobiologic concepts are fully discussed in reference to physical therapy and radiotherapy. The greater portion of this work is concerned with the different organ systems and the diseases therein which can be ameliorated or relieved by electrotherapeutic measures. In this respect the work is almost encyclopedic in extent. As a reference book it does not lack in completeness. As a textbook in electrotherapy and radiotherapy it will serve as a valuable guide to those familiar with the French language. The American reader will be struck particularly by the many diseases in which some form of electrotherapy is used. In this respect perhaps the work inadvertently suggests the long road of trial and error which has characterized so many attempts to apply electrotherapy or radiotherapy.

**Aids to Biochemistry.** By E. A. Cooper, D.Sc., F.I.C., A.R.C.S., and S. D. Nicholas, B.A., A.I.C., Lecturer in Chemistry, University of Birmingham. Second edition. Cloth. Price, \$1.50. Pp. 213, with 12 illustrations. Baltimore: William Wood & Company, 1938.

The sketchy text is intended to present the general principles of biochemistry to medical and science students who have already studied the subject by means of larger textbooks or lecture courses. It is "intended primarily for purposes of revision." It is also intended as a manual for experimental work. The work contains many inaccuracies. Among them are "the hexose molecules, for example, contain no less than four asymmetric carbon atoms" and "sixteen stereoisomeric aldoses are known." The treatment of the chemistry and importance of vitamins, of ketosis and antiketogenesis, male sex hormones, corpus luteum activity, enzymes, and acid-base equilibrium in the body is inadequate. The book would be of very little value as a "revision" for students of medicine in the United States.

**Focal Infection and Arthritis in the Light of Experiment.** By Ejnar Jarlöv, M.D., and Ove Brinck, M.D. Report from the Danish sections of the Association Internationale pour les Recherches sur la Parodontose and the Ligue Internationale contre le Rhumatisme. Paper. Pp. 94, with 22 illustrations. Copenhagen: Lassen & Stiedl, 1938.

After reviewing some of the earlier work on focal infection in arthritis, this little monograph, written in English, reports observations on experimental infection in rabbits. Streptococci of varying virulence were employed and it was found that strains of low virulence gave a greater infection percentage than those of high virulence. A measure of support is also given to the view that there are certain strains of streptococci with definite arthrotropic qualities. It is concluded that chronic joint disease which exactly resembles primary progressive polyarthritis (rheumatoid or atrophic arthritis) as well as osteo-arthritis can be produced experimentally on a purely infectious basis. As is well known, there are two schools of thought in this regard and these experiments definitely if not conclusively support the views of those who hold that rheumatoid arthritis and osteo-arthritis are not absolutely different and specific diseases. While there are some who believe that rabbits are entirely too obliging experimental animals for this type of experimental work, this report should be read by all those who are interested in this controversy.

**Der Operationskurs des Hals-, Nasen- und Ohrenarztes.** Von Prof. Dr. H. Beyer und Prof. Dr. A. Seiffert. Teil 1: Die Operationen am Ohr. Von Prof. Dr. H. Beyer. Second edition. Paper. Price, 24.50 marks. Pp. 278, with 317 illustrations. Leipzig: Curt Kabitzsch, 1938.

This brief yet comprehensive handbook of otologic surgery was planned as a guide for cadaver work as well as for the practicing specialist. The illustrations are new, clear and drawn from the original, occasionally international, sources. The explanatory text is accurate and simple, giving not only technical

details but also comparative statistics on various procedures. The author has brought his work down to date with the inclusion of Ramadier's and Lempert's paracarotid approach to the petrous apex, and of Holmgren's, Sourdille's and Wittmaack's operations for the relief of otosclerosis. More important, the usual operations are well illustrated with due regard to anatomic variations, and the technics suggested are those generally followed. There is a fair bibliography, as usual lacking reference to American work, and a brief subject index.

**Blodinamika proteidiv.** [By] N. B. Medvedeva. Pld redaktitsyu: O. O. Bogomoltsya. [Biodynamics of Proteins.] Paper. Price, 5 krb. 50 kopecks. Pp. 244. Kiev: Vidavnistvo Akademii Nauk URSR, 1938.

Nina Medvedeva is one of the most prolific research workers of the Ukrainian Academy of Sciences and claims to have separated a specific adrenal cortical hormone. The monograph at hand presents an extensive review of the chemical composition of proteins and their biologic properties. It is written in the Ukrainian.

**American Traumatic Guide.** [A National Survey in Compact Form of Traumatic Cases, Showing Physicians' Fees, Loss of Time and Percentages of Disability.] By William W. Bowen, M.D. Fabrikoid. Price, \$3. Pp. 80, with 23 illustrations. Des Moines, Iowa: American Publishing Co., 1938.

This is a compact survey of traumatic cases showing physician's fees, loss of time and percentage of disability.

The author has compiled charts and schedules in an effort to give physicians in general practice a reference that will help them in these situations. The schedules and percentages were compiled from reports of insurance companies, railroads, state insurance funds, United States Department of Labor and the experiences of specialists.

The first half of the book is purely anatomic. There is a glossary, definitions of terms used in the booklet and a report of workman's compensation, loss and extent of disability and by states.

The guide should be of value to surgeons doing casualty and compensation work and for claim superintendents, adjustments and legal and claim departments of insurance companies for setting up reserves and adjusting cases.

**Allgemeine Pharmakologie: Ein Grundriss für Ärzte und Studierende.** Von Dr. med. habil. Friedrich Axmacher, Dozent für Pharmakologie an der Medizinischen Akademie Düsseldorf. Paper. Price, 9.60 marks. Pp. 189, with 32 illustrations. Berlin: Julius Springer, 1938.

The author sees that general pharmacology is steadily replacing the old burdensome pharmacology with its immense number of drugs and recipes which the physician may rarely use. The object of the book is to present the general principles of pharmacology in a separate and short form, now lacking in the German language. The student may benefit from general pharmacology as much as from instruction in general pathology. The study must be pursued assiduously if the student is to gain fundamental conceptions of drug action. He discusses the absorption of drugs, their distribution in the body, excretion, relation of dose to effect, sensitivity of the organism, habituation, idiosyncrasy, fate of drugs in the body, synergism and antagonism, and chemical constitution in relation to action. The American student will find nothing new, either in method of presentation or in subject matter. All is to be found in the standard textbooks of pharmacology.

**Der Zyklus der Frau: Reform des Ehelebens.** Von Dr. Jules Samuels, Leiter der Einrichtung für Kurzwellentherapie, Amsterdam. Paper. Price, 4.50 guilders. Pp. 175, with 43 illustrations. The Hague: G. Naef, 1938.

The author of this book is trying hard to convince every one of his ideas. Within the last two years he has written three books and twenty-five articles in four different languages. Practically all the information imparted in this book is based on an instrument devised by the author and called a cycloscope. He first describes the anatomy of the pelvic organs. He then discusses endocrinology from a gynecologic point of view. There follows a description of the cycloscope, a simple instrument by means of which he claims he can study all the essential hormone processes in the body. By the use of this instrument, according to the author, it is possible for the first time to determine exactly when a woman ovulates. The author maintains that young girls and young women ovulate three times every month and that after a certain age or after a labor women ovulate

twice a month. Likewise the author claims that by means of this instrument it is possible to determine a pregnancy a few days after fertilization, even before a menstrual period is missed. Furthermore the instrument permits graphic demonstration of all ovulatory and menstrual disturbances. The essential part of the cycloscope is a spectroscope, and the purpose of the instrument is to study the reduction stripes of the oxyhemoglobin in the blood and the appearance of the first methemoglobin coloring. A great deal of the contents of the book are duplicated in another of the author's books, "Endogene Endokrinotherapie in der Gynäkologie," which was recently reviewed in *THE JOURNAL*. The author's claims are startling. Thus far no one has published any confirmatory reports, although the author says that Gauss of the Würzburg clinic, through his assistant Kastendieck, reported that he had investigated Samuels' cycloscopic methods of investigation and confirmed a few of his conclusions.

**Treatment in General Practice: The Management of Some Major Medical Disorders.** Volume II. Articles Republished from the *British Medical Journal*. Second edition. Cloth. Price, 10s. 6d. Pp. 436, with illustrations. London: H. K. Lewis & Co., Ltd., 1938.

This edition so soon after the appearance of the first is largely due to the application of sulfanilamide and similar compounds in the treatment of streptococcal and other infections. The thoroughly practical nature of this relatively small book by numerous authors on diseases of the respiratory tract, acute specific fevers and cardiovascular diseases makes it merit a place in the library of every practicing physician.

**Handbook of Physiology and Biochemistry.** By the late W. D. Halliburton, M.D., LL.D., F.R.C.P., and R. J. S. McDowall, M.D., D.Sc., F.R.C.P., Professor of Physiology, University of London, King's College, London. Thirty-fifth edition. Cloth. Price, \$5.50. Pp. 973, with 373 illustrations. Philadelphia: P. Blakiston's Sons & Co., Inc., 1937.

It is unusual for a scientific textbook to go into its thirty-fifth edition, which this handbook of physiology has done. It is still a popular book. The intervals between the last few editions have become shorter, although the number of books printed each time has been the same. New points have been added about the humoral transmission of the nerve impulse, vitamins, enzymes and sex hormones. The several sections on lymph formation, the pituitary, metabolism and diet have been completely remodeled. Some things which in former editions seemed important have been given less attention. The editors have kept in mind the needs of medical students preparing for examinations, and that accounts for some limitation of material and probably also for the popularity of the book. William S. Kirkes of St. Bartholomew's Hospital, a student of James Paget, edited the first edition in 1848. Kirkes thanks Sir James Paget for allowing him the free use of his lecture notes. With the fourth edition Mr. Savory, a lecturer on comparative anatomy and physiology at St. Bartholomew's, became the author. With the sixth edition came a new associate editor, Mr. Morant Baker, demonstrator of anatomy. In 1896, when a new edition was necessary, Professor Halliburton accepted the position, thus severing the long association between the book and St. Bartholomew's Hospital. The book now entered a new era of prosperity and in twenty-nine years seventeen editions were published.

**The Influence of X-Radiation on the Development of Immunity to Heterologous Transplantation of Tumors.** By Johannes Clemmesen. Denne Afhandling er af det lægevidenskabelige Fakultet antaget til offentlig at forsvares for den medicinske Doktorgrad, København. The translation into English by Robert Fraser. Paper. Price, 10 Danish kroner. Pp. 160, with 13 illustrations. Copenhagen: Levin & Munksgaard; London: Oxford University Press, 1938.

This small paper covered book will be valuable to those who are interested in the experimental phase of cancer work, because it contains a critical analysis of the experimental background as it applies to the transplantation of various tumors and also a detailed report of the author's own experiments. Clemmesen apparently inclines toward the genetic theory of cancer transmission and therefore appears to believe that mutation is perhaps the main factor in and the best explanation of most of the observations made in experimental cancer. To radiologists this report should be interesting because in his own experiments the author has used roentgen rays to a considerable extent in order to reduce the resistance of animals to transplanted tumors.

**Archiv und Atlas der normalen und pathologischen Anatomie in typischen Röntgenbildern. Der Kreuzschmerz in seiner Beziehung zur Wirbelsäule.** Von Priv. Doz. Dr. J. E. W. Brocher. Mit einem Vorwort von Prof. Dr. Volhard. Fortschritte auf dem Gebiete der Röntgenstrahlen, Ergänzungsband LV. Herausgegeben von Prof. Grashey. Paper. Price, 19.50 marks. Pp. 91, with 101 illustrations. Leipzig: Georg Thieme, 1938.

This interesting monograph on backache and sciatica contains discussions of anomalies of the spine, congenital defects, osteoporosis, lumbago and sciatica. It provides a clinical investigation of spina bifida, sacralization, spondylolisthesis and the gynecologic aspects of the subject. There is a foreign bibliography. The illustrations of vertebral pathologic changes are well done and highly instructive.

**Oftalmologia del paesi caldi.** Dal Prof. Vittorio Ruata, docente di patologia e Clinica oculistica nella R. Università di Roma. Cloth. Price, 45 lire. Pp. 362, with 96 illustrations. Milan: Ulrico Hoepli, 1938.

This comparatively small book deals with the ophthalmologic conditions encountered in practice in the tropical climates and is based on the personal experiences of the author. It is divided into nine chapters, five of which are devoted exclusively to the questions of oriental ophthalmology. The effects of intense heat and sunlight on the eyes are peculiarly tropical, as are the effects of the living conditions. To the ophthalmologists of the temperate zones, animal parasites are an almost unknown quantity, particularly the various forms of *Filaria*; but to the ophthalmologists in tropical countries the descriptions and illustrations that Ruata presents are of the utmost value. The chapters that deal with the bacteriology of the eye and the usual forms of conjunctivitis present nothing of unusual interest. A fairly long chapter is devoted to trachoma and offers a fairly good summary of the well known facts, except that the part devoted to treatment is rather skimpy. The diseases of the cornea and of the fundus again present the conditions that are peculiar to tropical ophthalmology. The final short chapter on surgery could well have been omitted. The black and white illustrations throughout are uniformly poor, except those depicting the various animal parasites. The colored illustrations, on the other hand, are uniformly good. Appended to each chapter is a good working bibliography. To one who reads Italian and who practices in tropical climates, the book is valuable.

**Dysmenorrhoea: Its Aetiology, Pathology and Treatment.** By Albert A. Davis, M.D., Ch.M., F.R.C.S., Hon. Gynaecological Surgeon to Outpatients, the French Hospital, London. Cloth. Price, \$4.50. Pp. 254, with 35 illustrations. New York, London & Toronto: Oxford University Press, 1938.

This subject, surrounded by so many theories as to both etiology and treatment, has been handled admirably by Davis in this treatise. The total amount of incapacity and the days of disability among women affected by dysmenorrhea each month are truly of vast economic as well as physical importance and more than warrant the attention which has been given the subject by many writers. Davis's book reviews the historical phases and the innumerable attempts at classification of dysmenorrhea. He finally sums up the latter as being symptomatically "spasmodic" and "congestive" or pathologically "primary" and "secondary." His summation along these lines is primarily for therapeutic reasons. He continues with an analysis of its etiology, including the hormone and neurogenic theories and a comprehensive discussion of the immediate causes of the pain. Nearly half the book is devoted to treatment, logically based on etiology as far as possible. For the cases requiring surgical treatment he gives in detail the technic of alcohol injection of the pelvic plexus and of resection of the presacral sympathetic nerve plexus, with excellent illustrations. The book is warmly recommended to the gynecologist and will prove of value likewise to the general practitioner.

**Paragilusniy tuberkuloz u doroslikh.** [By] N. S. Morozovskiy i D. P. Aleksandrovskiy. [Parahilar Tuberculosis in Adults.] Paper. Price, 3 krb. 50 kopecks. Pp. 139, with 22 illustrations. Kiev: Derzhamedvidav, 1937.

This is a monograph emanating from the Kiev Tuberculosis Institute. The monograph is a clinico-anatomic study dealing with hilus tuberculosis as the primary focus of tuberculous infection. It offers nothing that is not already known on the subject and is in the main a corroboration of the recent studies of Ranke. It is written in the Ukrainian.

**Clinical Roentgenology of the Digestive Tract.** By Maurice Feldman, M.D., Assistant Professor of Gastroenterology, University of Maryland, Baltimore. Cloth. Price, \$10. Pp. 1,014, with 358 illustrations. Baltimore: William Wood & Company, 1938.

This book covers completely the whole subject of roentgenology of the gastrointestinal tract. It represents a tremendous amount of work on the part of the author, not alone because of the large field it covers but particularly because of the enormous amount of reading the author has done, as is shown by the extremely large bibliography presented. The subject matter is covered completely and well. There are over 350 illustrations, a few diagrams, the rest reproductions of x-ray films, and almost 200 charts tabulating the reports of the numerous authors who are quoted. Dr. Feldman in his preface states that he is presenting a clinicoroentgenologic consideration of the gastrointestinal tract. This is borne out by the fact that each disease described has its clinical side presented sufficiently to allow both the clinician and the roentgenologist to obtain a fairly complete picture of the whole subject. Of course, this accounts for the size of the book. While this may have its good side, it seems that the clinical side could be condensed considerably without sacrificing its value. No attempt is made to decry the value of this work by calling attention to a few points. In describing the types of stomachs in their relation to the build of the individual it might be advisable to call attention to the work of Moody, who has shown in his study of a large number of students that there is frequently no conformity of the type to the build. Hurst and Stewart's book on duodenal ulcer is not referred to in that caption of the author's work, although references to Stewart do appear. Gastroscopists do not always find a relationship between the gastric folds observed gastroscopically and roentgenologically. It would seem in the last analysis that when the examination is not contraindicated gastroscopy should be the method of choice for diagnosis of gastritis and the character of the rugae. There are a few errors in grammar and in spelling of proper names in the first part of the book which were overlooked. One reference to peptic ulcer, described as gastric ulcer, was quoted wrongly since the type of ulcer described was actually duodenal. The book as a whole is well written, has a large index, and can be recommended for the use of clinicians and roentgenologists.

**20 rokov radyanskoj meditsini na Ukraïni.** Zbirnik za redaktsiynu O. O. Bogomoltsya, M. D. Strazhesko i S. S. Kagan. [20 Years of State Medicine in Ukraine.] Cloth. Price, 20 krb. Pp. 416, with illustrations. Kiev: Derzhavne Medichne Vidavnistvo, 1938.

This is a volume edited by the academicians O. O. Bogomolets, M. D. Strazhesko and Prof. S. S. Kagan and devoted to the development of medical service in Ukraine in the past twenty years. It is in the Ukrainian and unlike most contributions of this type is not accompanied by a synopsis in English, French or German. It deals with the development of public health and the growth of dispensaries, hospitals, sanatoriums and lying-in hospitals. One is impressed with the quantitative growth of medical service particularly in the fields of obstetrics, pediatrics and tuberculosis. It is difficult, if not impossible, to form an opinion from the contents of the volume as to the quality of the service.

**Outlines of Biochemistry: The Organic Chemistry and the Physicochemical Reactions of Biologically Important Compounds and Systems.** By Ross Alken Gortner, Chief of the Division of Agricultural Biochemistry, University of Minnesota, Minneapolis. Second edition. Cloth. Price, \$6. Pp. 1,017, with 165 illustrations. New York: John Wiley & Sons, Inc.; London: Chapman & Hall, Limited, 1938.

The second edition is of the same high standard of excellence as the first and needs no further recommendation as a useful book. The first third of the book is taken up with biophysical chemistry, including chapters on hydrogen ion concentration, oxidation-reduction, osmotic pressure and electrical conductivity, and the remainder on colloids. The rest of the book is on proteins, carbohydrates, including glycosides, lignin and tannins, plant and animal pigments, lipids and essential oils, hormones, vitamins and enzymes. These subjects are treated in a masterly manner and the book is very readable. For those who wish to use it for reference, however, it may be indicated that inositol, phytin and hexosephosphates are taken up with the compound lipids. Since the author does not include co-authors on the title page, we assume that he is

responsible for the entire text. It may be noted that on page 867 vitamin F is thrown out of the list on the ground of commercial exploitation. The reviewer has not noticed any lack of commercial exploitation of the other vitamins.

**Der Rheumatismus: Sammlung von Einzeldarstellungen aus dem Gesamtgebiet der Rheumaerkrankungen.** Herausgegeben von Professor Dr. Rudolf Jürgens, Stellv. Direktor der Universitätsklinik für natürliche Heil- und Lebensweisen, Berlin. Band VII: Rheumatische Kreislaufschädigungen. Von Dr. Siegfried Dietrich, Dozent für innere Medizin, II. Medizinische Klinik der Charité, Berlin. Mit einem Geleitwort von Prof. Dr. G. von Bergmann, Direktor der II. Medizin. Univ.-Klinik, Berlin. Boards. Price, 9 marks. Pp. 204, with 34 illustrations. Dresden & Leipzig: Theodor Steinkopff, 1938.

This monograph is one of the series on various aspects of rheumatism written by different German authorities. Dietrich has reviewed the literature on the effect of rheumatism, especially rheumatic fever, and on the circulatory apparatus and has expressed some of his own opinions. There is an excellent bibliography attached.

**Nervova sistema i vuglevodnyi obmin u bezkhibetnikh.** [By] M. V. Ermakov. Pld redaktsiynu O. O. Bogomoltsya. [Nervous System and Carbohydrate Metabolism of Invertebrates.] Paper. Price, 3 krb. Pp. 96, with 16 illustrations. Kiev: Vidavnistvo Akademii Nauk URSR, 1938.

The monograph by Prof. M. V. Ermakov in Ukrainian is concerned with the elucidation of the development in the phylogensis of the relationship between the nervous system and blood sugar level in a number of invertebrates. The author found that the nervous system begins to assume a role in the regulation of hemolymph sugar at that stage of evolution in which there appears in the nervous system a more or less differentiated sympathetic division. Such is the case in certain mollusks, lobsters, crabs, scorpions and insects. The monograph presents an interesting contribution to the problem of evolutionary physiology.

**Normale und krankhafte Steuerung im menschlichen Organismus.** Fünf- und zwanzig Vorträge gehalten in dem internationalen Fortbildungskurs der Berliner Akademie für ärztliche Fortbildung von 26. bis 31. Oktober 1936. Von Prof. Dr. H. W. Bansl, et al. Zusammengestellt von Professor Dr. C. Adam. Paper. Price, 12 marks. Pp. 302, with 39 illustrations. Jena: Gustav Fischer, 1937.

This is a collection of lectures about what we know at present concerning several subjects. Such subjects are included as the autonomic nervous system, endocrines, acid-base balance, central nervous system, psychic phenomena, sleep, circulation, nutrition, growth, allergy and inflammation. The essays are general in character and are not critical contributions to the subjects in question. Rather they are meant to serve as short reviews for the German practitioner to bring his information down to date. The volume will be of little or no interest to American physicians, since there are similar reviews in English.

**Biography of the Unborn.** By Margaret Shea Gilbert. Cloth. Price, \$1.75. Pp. 132, with 36 illustrations. Baltimore: Williams & Wilkins Company, 1938.

The author has attempted to present to the lay reader in intelligible terms the manner of the development of a fetus in utero. She relates this in the chronological pattern of the nine calendar months which comprise the normal period of human development before birth. She has succeeded in writing an interesting story of this complicated subject, although at times she is quite flowery in her descriptions and explanations. The illustrations greatly help to clarify the text. A relatively large proportion of our population is avid for factual and pseudo-factual information about the process of childbirth and many of these persons will find this book interesting and instructive.

**Kollapstherapie der Lungentuberkulose.** Herausgegeben von Walter Schmidt. Mit einem Geleitwort von Ludolph Brauer und Ferdinand Sauerbruch. In two parts. Paper. Price, 116 marks. Pp. 528; 531-1135, with 1,077 illustrations. Leipzig: Georg Thieme, 1938.

This is an elaborate work on collapse therapy in two volumes. The introduction by Ludolph Brauer and Ferdinand Sauerbruch in itself is a good recommendation for this work. Numerous authors have contributed chapters, and every phase of collapse therapy is discussed. The work of a number of American authors is cited, as well as of those from various other nations. These volumes are profusely illustrated and contain an extensive bibliography. They can be recommended to all physicians interested in collapse therapy.

## Bureau of Legal Medicine and Legislation

### MEDICOLEGAL ABSTRACTS

**Malpractice: When Judgment for Fee Does Not Bar Subsequent Malpractice Suit.**—McDowell, a licensed physician, sued Marchant to recover his fee for operating on Marchant's wife. Marchant filed a counterclaim, asking damages for a burn sustained by his wife, so he claimed, who, when on the operation table and while under the anesthetic, extended her hand and touched a hot radiator. The jury rendered a verdict for the physician for his fee but disagreed as to the counterclaim, whereupon the court "dismissed the counterclaim, but not on the merits." Judgment was then entered for the physician.

Later Marchant brought, in the city court of Buffalo, an action against the physician to recover damages for the burn sustained by his wife. The physician moved that the action be dismissed, relying on *Blair v. Bartlett*, 75 N. Y. 150, 31 Am. Rep. 455, in which the court said:

It must be considered as settled in this state, that a judgment in favor of a physician and surgeon for his professional services, rendered by a court of competent jurisdiction, in an action in which the defendant appeared and answered, setting up a defense which he maintained at the trial . . . is a bar to an action for malpractice by that defendant against that physician and surgeon for malpractice in rendering those services.

The facts involved in that case, said the court, differ essentially from those in this case. In the case cited, a complete trial had been had, a full opportunity had been given to the defendant to appear and defend, and a judgment was rendered. In the present case the jury considered two matters, the professional sufficiency and value of the services rendered by the physician and the alleged negligence of the physician in permitting the operating table to be too near the radiator. Obviously, the court said, the position of the operating table presented a problem which had attached to it no element of professional technic; it was a matter of commonplace negligence, involving no failure in subtle niceties of the performance expected and received from medical men as such. The jury, by reporting the disagreement in their verdict with respect to the counterclaim, indicated that they had reached no decision concerning the question. Marchant, then, has had no opportunity of having this essential phase of his case judicially determined.

The court believed, therefore, that Marchant should be given an opportunity to litigate the question as to the negligence "in this radiator propinquity circumstance" and therefore denied the motion of the physician to dismiss the action.—*Marchant v. Buffalo General Hospital* (N. Y.), 3 N. Y. S. (2d) 496.

**Compensation of Physicians: Liability of Employer for Medical Services Rendered Employee.**—Perry was seriously injured in the course of his employment. At the apparent suggestion of his employers that hospitalization was necessary, he was taken to a hospital in a neighboring town and the plaintiff physician called to attend him. After diagnosing Perry's condition, the physician visited the employers to ascertain who would be responsible for his bill and was assured that his bill "would be taken care of all right," that "the insurance company (with whom the employers carried a policy of workmen's compensation insurance) would take care" of it. The physician then undertook to care for Perry. Perry never instituted proceedings under the Missouri workmen's compensation act, to which the employers and the worker were subject, and the physician's bill was not paid. The physician then sued the employers at common law to recover his fees. The defendants contended that the court was without jurisdiction since the workmen's compensation commission of Missouri was the only tribunal authorized by law to pass on the matter. The court, however, sitting without a jury, entered judgment in favor of the physician and the defendants appealed to the Kansas City (Missouri) court of appeals.

Apparently proceeding on the theory that a physician could not have a claim for services litigated before the compensation commission independently of a claim for compensation filed by

the injured workmen, the court believed that to hold, as the defendants contended, that exclusive jurisdiction to pass on a physician's bill for services rendered an injured workman was vested in the compensation commission would permit employers, by settling with their injured workers without recourse to the commission, to defeat obligation for services rendered at the employer's request. Admittedly, said the court of appeals, Perry and his employers were operating under the provisions of the Missouri workmen's compensation act and Perry suffered an injury arising out of and in the due course of his employment. The employers, therefore, were in no position to assert that there was no duty on them to provide medical, surgical and hospital treatment. This duty would render them liable to pay a physician whom they called to care for their injured workman even though the rule of law is that when a physician is called at the mere request of a third party, on whom there rests no obligation to provide medical care, no contract to pay for the services is implied. Whether or not the employers in this case assumed an obligation to pay the physician was a question of fact for the trial court to determine and the court of appeals believed that sufficient facts were in evidence to support an inference that the employers had assumed that obligation. The court further believed that the fact that the employers expected the insurance company to pay would not alter the situation. The judgment in favor of the physician was accordingly affirmed.—*Gronoway v. Markham* (Mo.), 115 S. W. (2d) 136.

**Malpractice: Failure to Use Roentgenograms as Diagnostic Aid.**—The defendant did an open reduction of the patient's fractured ankle in November 1927, using a metal screw to keep the fragments in apposition. Seven years later, in November 1934, the patient again consulted the defendant, complaining of pain in the ankle that had been fractured. The physician, attributing the trouble to arthritis, wrapped the ankle with adhesive tape and adjusted an arch support which he had made for the patient at the time he reduced the fracture. About a week later he removed the adhesive tape. The ankle became more painful and finally, in January 1936, the patient went to another physician, who discovered through the use of roentgenograms that there had been some necrosis of the bone around the screw. The screw was removed and the patient made an uneventful recovery. Later the patient and her husband instituted a malpractice action against the defendant. The trial court at the close of the plaintiff's evidence directed a verdict for the physician, and the plaintiffs appealed to the Supreme Court of Arizona.

A physician to be liable for malpractice, said the court, must have done something in his treatment of his patient which the recognized standard of good medical practice in the community in which he is practicing forbids in such cases, or he must have neglected to do something which such standard requires. That standard must be shown by affirmative evidence and negligence on the part of a physician in departing from the standard must be established by expert medical testimony, unless the negligence is so apparent that a layman would have no difficulty in recognizing it. The testimony of other physicians that they would have followed a course of treatment different from that followed by the defendant is not sufficient to establish malpractice unless it also appears that the course of treatment followed deviated from one of the methods of treatment approved by the standard in the community. The treatment by the defendant in the present case, said the court, consisted of an "ordinary examination" of the ankle, the smoothing of an arch support which she was then wearing, the wrapping of the ankle with adhesive tape, and the removal of the tape about a week later. The only testimony bearing on medical standards or the treatment accorded the patient in November 1934 was that of the defendant himself and of the physician who removed the screw. The defendant testified that he did what was required by the patient's condition as it existed when he treated her in November 1934. The other physician could not state how long prior to January 1936 the screw should have been removed. He stated however that, if the ankle had been in the same condition in November 1934 as it was when he operated in January 1936, the screw should have been then removed but that it was impossible for him to testify as to when the condition justifying the removal

arose. He further stated that if he had been in the position of the defendant when the patient called in November 1934 his conclusion, like the defendant's, would have been that arthritis in the ankle joint was causing the pain but that he would not have been fully satisfied without having a roentgenogram made of the ankle. He further testified that the method of uniting fragments of bone used by the defendant was a standard one and that the screw was not removed, as a rule, unless it made trouble.

The plaintiffs based their claim of negligence almost entirely on the failure of the defendant to take a roentgenogram of the patient's ankle in November 1934. They urged that a failure to do so was such obvious negligence that even a layman knows that it was a departure from the proper standard. The Supreme Court, however, could not agree with this contention. It is true, said the court, that most laymen know that roentgenograms usually offer the best method of diagnosing physical changes of the interior organs of the body, and particularly of the skeleton, short of an actual opening of the body for ocular examination, but laymen cannot say that, in all cases in which there is some trouble with the internal organs, it is a departure from standard medical practice to fail to take a roentgenogram. In view of the testimony in the present case as to the arthritis from which the patient was suffering and which the second physician testified would have been his first thought as to the cause of the patient's pain in 1934, the court thought it was going too far to say that the failure to take a roentgenogram at that time was so far a departure from ordinary medical standards that even laymen would know it to be gross negligence. Since there was insufficient evidence in the record to show that the defendant was guilty of malpractice, the trial court properly directed a verdict for the physician. The judgment in favor of the physician was accordingly affirmed.—*Boyce v. Brown (Ariz.)*, 77 P. (2d) 455.

**Hospitals: Criteria of Charitable Status of a Hospital.**—If the purpose of an institution, said the Supreme Court of Arizona, is one which is recognized in law as charitable, and if it is not maintained for the private gain, profit or advantage of its organizers, officers or owners, directly or indirectly, the institution is properly characterized as a charitable one, notwithstanding the fact that it charges for most, if not all, of the services which it may render, so long as its receipts are devoted to the necessary maintenance of the institution and the carrying out of the purpose for which it was organized. The extent of the free services rendered by a hospital offers no adequate test of the charitable status of the hospital, the court said.

In the present case a baby was burned by negligent exposure to a hot water bottle in the appellant hospital. The contention that was advanced on behalf of the infant, in a suit against the hospital, was that even if it should be admitted that the hospital was a charitable institution, nevertheless it was bound to use due care in the selection of its employees and if it failed to do so it is liable for the negligence of such employees. The court, however, was unable to discover any evidence in the record sufficient to bring the case within the rule correctly stated in the contention. There was nothing to show which particular employee was guilty of the undoubted negligence which caused the injury. The record did show that three weeks prior to the injury in the present case another baby was burned in a somewhat similar manner, but this evidence was considered by the court entirely insufficient to establish that, even assuming that the same nurse was responsible for the two injuries, the hospital did not use due care in her selection and retention. It is true, the court pointed out, that the doctrine of *res ipsa loquitur* is properly applicable in such circumstances. But, the court continued, it was shown in the present case that all the nurses employed by the hospital were authorized by the state of Arizona to practice their profession. Where it is shown by positive evidence that the nurses employed by a hospital are of this character, any presumption that may have arisen from the doctrine of *res ipsa loquitur* that the hospital has not used due care in the selection of a given employee is destroyed, and in order to overcome such evidence there must be at least an affirmative showing that the hospital had knowledge of the previous negligence of the nurse and, notwithstanding such

knowledge, continued her employment. Since there was no evidence that the hospital ever knew that any one of its nurses was not competent in all respects, and since the record showed affirmatively that the hospital was, within the true meaning of the phrase, a charitable institution, it was not legally responsible for the unfortunate situation involved in the present case. The judgment of the superior court against the hospital was therefore reversed and the case remanded with instructions to enter judgment for the hospital.—*Southern Methodist Hospital and Sanatorium of Tucson v. Wilson (Ariz.)*, 77 P. (2d) 458.

**Workmen's Compensation Act: What Constitutes a Hernia.**—The claimant in this case contended that in the course of his employment he fell and immediately experienced a sharp pain in his left groin. He reported the accident to his foreman and was referred to the first aid station. What was found there is not shown by the record, but the claimant applied for compensation, alleging that an inguinal hernia had resulted. From an order of the workmen's compensation commission reversing an award that the deputy labor commissioner had entered in favor of the claimant, the claimant appealed to the Supreme Court of Michigan.

At a hearing before the deputy commissioner a physician who had examined the claimant a few days after the alleged accident and again about two months later testified that he had found on both occasions a left indirect inguinal hernia. On behalf of the employer, however, a physician who had examined the claimant in the interval between these two examinations testified that he had found an enlarged inguinal ring on each side, the ring on the left side being somewhat more enlarged than that on the right, but that he found no hernia. The condition that he found might be referred to, he said, as a potential hernia, but in his opinion nothing is a hernia unless there is a protrusion of a viscus or organ from its natural cavity. There was no protrusion of a viscus in the present case, although there was "a sharp mass by inserting your fingers in the rings and getting up on to the abdominal cavity." Some men, said this witness, call any such sharp mass a hernia, but others refuse to call it a hernia until after it has descended. In this case, in the opinion of this witness, the viscus had not descended through the rings.

Quoting its own decision in *Robbins v. Original Gas Engine Co.*, 191 Mich. 122, 157 N. W. 437, 438, the court said that in that case—

All the experts seem to agree that the visible evidence of the hernia is the protrusion through the inguinal ring of the peritoneum and its contents; "the hernia is the peritoneum going through, accompanied by the intestines or some other substance."

In the present case, said the Supreme Court, there was no protrusion through the internal inguinal ring and the evidence sustained the finding of the Commission on Labor and Industry holding that the claimant had a potential hernia or a predisposition to hernia. The order of the commission denying compensation was affirmed.—*Cessante v. Ford Motor Co. (Mich.)*, 278 N. W. 671.

## AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1928 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (\*) are abstracted below.

### American Heart Journal, St. Louis

16: 387-514 (Oct.) 1938

Infarction of Lateral Wall of Left Ventricle: Electrocardiographic Characteristics. F. C. Wood, C. C. Wolferth and S. Bellet, Philadelphia.—p. 387.

\*The Heart in Pneumoconiosis. C. B. Coggin, D. E. Griggs and W. L. Stilson, Los Angeles.—p. 411.

The Social Component in Heart Disease. Ethel Cohen, Boston.—p. 422.

Study of Chest Leads of Electrocardiogram with an Evaluation of Positions of Precordial Electrode. J. C. Edwards and J. B. Vander Veer, Philadelphia.—p. 431.

Cardiac Output in Compensation and Decompensation in the Same Individual. J. McGuire, Rose Shore, V. Hauenstein and F. Goldman, Cincinnati.—p. 449.

Effects of Intravenous Administration of Digitalis Bodies on Patients with Transient Ventricular Fibrillation. S. P. Schwartz and A. Jezer, New York.—p. 462.

Factors of Error in Blood Pressure Readings: Survey of Methods of Teaching and Interpretation. I. S. Wright, R. F. Schneider and H. E. Ungerleider, New York.—p. 469.

Effect of Valvular Heart Disease on Dynamics of Circulation: Observations Before, During and After Occurrence of Heart Failure. H. J. Stewart, J. E. Deitrick, R. F. Watson, C. H. Wheeler and N. F. Crane, New York.—p. 477.

**Heart in Pneumoconiosis.**—Coggin and his co-workers ascertained the incidence of pulmonary cardiac disease in 205 cases of pneumoconiosis, its frequency as a cause of congestive failure and whether the cardiac changes could be detected clinically and roentgenologically. Of these cases 102 occurred in the 19,800 necropsies performed at the Los Angeles County Hospital in the last twenty years, and in the remaining 103 cases there was an adequate history of exposure to silica, and roentgenograms showed the characteristic pulmonary changes of pneumoconiosis. Hypertrophy of the right ventricle was present in 44.1 per cent of the 102 cases that were studied post mortem. If hypertrophy of both ventricles is included, right ventricular hypertrophy occurred in 58.8 per cent of the cases. Definite congestive cardiac failure was found more frequently in these cases (51 per cent) than was tuberculosis (40.2 per cent). It was usually a terminal event. Therefore when it occurs clinically the prognosis is grave. If pneumoconiosis is uncomplicated by tuberculosis or other pulmonary infection, death from cardiac failure is to be expected. The clinical diagnosis of cor pulmonale in pneumoconiosis is suggested by accentuation of the pulmonic second sound, marked cyanosis, right axis deviation in the electrocardiogram and characteristic changes in the postero-anterior roentgenogram; that is, prominence of the pulmonary conus, elevation of the cardiac apex and an increase of the broad or basal diameter in the absence of enlargement of other diameters.

16: 515-642 (Nov.) 1938

Dynamics of Hypertension. C. J. Wiggers, Cleveland.—p. 515.

Treatment of Angina Pectoris by Methods Which Appear to Promote More Adequate Filling of the Heart: Presidential Address. W. J. Kerr, San Francisco.—p. 544.

Vascularization of Atherosclerotic Lesions. T. Leary, Boston.—p. 549.

Use of Metrazol in Complete Heart Block with Adams-Stokes Syndrome: Report of Four Cases. H. C. Lueth, Evanston, Ill.—p. 555.

\*Use of Quinidine in Treatment of Arrhythmias and Tachycardias Caused by Digitalis Intoxication: Note on Possibility of "Spontaneous Redigitalization" Following Rapid Diuresis. B. A. Gouley and L. Soloff, Philadelphia.—p. 561.

Acute Nephritis with Cardiac Failure: Report of Two Cases. A. E. Feller, Iowa City, and H. M. Hurevitz, Davenport, Iowa.—p. 568.

New Sensitive Recording Oscilloscope. I. Friedman, L. H. Ott and A. W. Oughterson, New Haven, Conn.—p. 575.

**Quinidine in Digitalis Arrhythmias.**—Digitalis, under certain conditions, may accelerate cardiac failure in a manner so insidious that the undesirable effect may be overlooked entirely. The electrocardiographic changes may be the first

to show evidence of poisoning and the most reliable guides to the use of the drug. Gouley and Soloff report two cases in which serious digitalis poisoning manifested itself by cardiac arrhythmias, nodal and ventricular tachycardia and auriculo-ventricular dissociation. These disturbances continued despite withdrawal of the drug. Quinidine therapy was useful in restoring normal rhythm in one case but was of no avail in the other. Its failure in this case was believed to be due to inadequate dosage and to the state of advanced cardiac decompensation. Another factor, however, was a cumulative effect of digitalis, possibly caused by a mobilization of the drug in the circulation during diuresis.

**Relation of Bacillary Dysentery to Colitis.**—Brown and Bagen discuss the late results of 140 cases of bacillary dysentery, studied previously by Kinsella, more than sixteen years since the epidemic. Fifteen patients died during the epidemic. Twenty-three patients could not be traced but they apparently were well when they were dismissed. Twenty-four patients died months or years after their dismissal. These patients also apparently were well and had no intestinal symptoms traceable to the epidemic. The stools of forty-five patients yielded *Shigella paradysenteriae*. Seventy-seven patients are known to have lived for from one to seventeen years and did not have any intestinal symptoms after their dismissal. A form of chronic ulcerative colitis developed in only one of the patients. The incidence of intestinal ulceration of a chronic type following large epidemics of dysentery during wars is exceedingly small. Intensive cultural and serologic investigations of the lesions of typical chronic thrombo-ulcerative colitis for organisms of the *Shigella* variety have yielded largely negative results. The results of serologic studies in cases of regional enteritis have been inconclusive so far. Sufficient evidence is not at hand to consider the *Shigella* group of organisms as the cause of chronic thrombo-ulcerative colitis. If chronic ulcerative disease of the intestine develops only in one of every 100 cases of acute dysentery, the suffering in that one case warrants every possible effort to stamp out dysentery.

**Vitamin K in Hemorrhagic Tendency in Jaundice.**—Snell and his co-workers administered to more than thirty patients, most of whom had obstructive jaundice, from 200 to 1,000 mg. of concentrates containing vitamin K prepared from putrefied fish meal, together with bile salts or human bile obtained from a biliary fistula. The bile or bile salts were mixed with cold pineapple juice and given by mouth in doses of from 75 to 150 cc. before each meal. A typical response of both prothrombin time and the concentration of prothrombin to vitamin K and bile when administered together has been

obtained repeatedly. The prothrombin time decreased to within normal limits within a period of from twenty-four to seventy-two hours and the prothrombin itself showed a quantitative increase. Active bleeding has at the same time been controlled in several instances. It appears that the vitamin alone will not accomplish this result if bile is excluded from the intestine, while bile or bile salts have some definite effect, presumably because these substances facilitate absorption of the vitamin which is already present in the intestinal tract. In the presence of injury of the liver larger amounts of vitamin K are required to achieve the desired effect. Presumably the chemical laws governing mass action are operative in this connection. This treatment offers considerable hope for the ultimate control of the hemorrhagic diathesis in jaundiced persons.

**Carbohydrate Metabolism in Hepatitis.**—Conn and his colleagues studied the nature of the disturbed carbohydrate metabolism associated with chronic ascending infectious hepatitis in six cases. All exhibited periods of spontaneous hypoglycemia. The glycemic response to ingested dextrose was grossly abnormal. A short period of fast or of carbohydrate restriction resulted invariably in severe hypoglycemia. Data obtained by indirect calorimetry indicated normal oxidation of dextrose under a variety of conditions. Besides the disturbance in carbohydrate metabolism, microscopic examination of biopsy or necropsy material showed chronic cholecystitis and ascending infectious hepatitis leading to early biliary cirrhosis. The authors believe that this disturbance in carbohydrate metabolism, although common, is frequently unrecognized or interpreted wrongly. In the early stage the glycogenic function of the liver appears to be seriously impaired. Since in their cases a hyperglycemic response occurred after ingestion of dextrose and since dextrose was oxidized at the normal

rate under the same conditions, the excess dextrose in the blood stream must be explained by impaired glycogenesis. They believe that this impairment in glycogenesis is one of rate rather than one of total disability, since the blood sugar returns to the fasting level in from four to five hours after ingestion of dextrose and since removal of dextrose is not explained by increased oxidation. The slow rate of glycogenesis accounts for the prolonged hyperglycemia. This delayed removal from the blood stream of absorbed carbohydrate results in postprandial hyperglycemia and glycosuria. Recovery of the glycogenic function appears to parallel the disappearance of the active infection. With the involvement of the glycogenolytic function of the liver, periods of hypoglycemia become manifest. This may be easily mistaken for hyperinsulinism. Respiratory data obtained during the hypoglycemic phase of this disturbance indicate that the low blood sugar levels are not the result of overoxidation of dextrose, as is the case in true hyperinsulinism. Hyperglycemia and glycosuria simulating diabetes mellitus may be a manifestation of one phase of hepatic dysfunction, and periodic spontaneous hypoglycemia may be the manifestation of further hepatic injury in the same patient at different times in the course of hepatitis. This suggests that the hypothetical conception of "dysinsulinism" is probably not the true underlying physiologic mechanism involved in many cases. Since oxidation of dextrose is normal in both the hyperglycemic and the hypoglycemic phases, it appears that hypo-insulinism alternating with hyperinsulinism is not the explanation. Hepatogenic hypoglycemia seems a more likely explanation. Even though the anatomic changes in the liver may be slight, the presence of chronic biliary infection may lead to functional disturbances in the metabolism of carbohydrate. A short period of fast or sharp restriction of the intake of carbohydrate gave rise in the authors' patients to extremely low blood sugar levels. It appears that this response to carbohydrate restriction is a sensitive test of the ability of the liver to deal normally with carbohydrate. Patients who suffer from periodic spontaneous hypoglycemia or whose dextrose tolerance curves are suggestive of diabetes in association with a low blood sugar level during fasting should be investigated for the presence of infection of the biliary tract. The condition may be greatly helped or even alleviated to the stage of clinical cure if the diagnosis of infectious hepatitis is made early and if appropriate surgical treatment is instituted.

**Fatal Anaphylactic Shock in Man.**—Ziskind and Schattenberg report a case of fatal anaphylactic shock following the second intravenous injection of a foreign protein. At necropsy the gross pathologic changes were congestion of the liver and more moderate congestion of the other organs. General enlargement of the lymph nodes and a persistent thymus gland were also noted. The significant microscopic changes were dilatation and congestion of the hepatic sinusoids and the alveolar capillaries of the lungs. There was an apparent relative increase in the leukocytes and the eosinophils within these vessels. The alveoli were compressed in some areas and dilated in others, and in some instances their walls were ruptured. The malpighian corpuscles of the spleen were increased in size and had large germinal centers. It is suggested that the mechanism of death of this patient was capillary dilatation, especially of the liver, with a corresponding fall in blood pressure and cardiac failure.

**Coronary Occlusion With and Without Pain.**—In a study of the clinical histories and necropsy data for 100 patients with proved coronary occlusion, Gorham and Martin found that forty-two patients had no cardiac pain, indicating a higher frequency of painless occlusion than is generally recognized. The fifty-eight patients who suffered from cardiac pain in a fatal attack tended to be younger. The peak mortality was ten years earlier in men than in women. A history of preceding attacks of anginal pain and of hypertension was more common, pain overshadowed dyspnea as a symptom and a pericardial friction rub was heard much more often. Actual thrombosis, acute infarction, acute pericarditis and milder grades of coronary sclerosis were encountered more frequently in this group of fifty-eight patients. The location of the infarct

and the rupture of the ventricle, with resulting hemopericardium, bore no relation to pain. The forty-two patients who had no pain in a fatal attack of coronary occlusion tended to be older than those who had pain, the peak mortality was a decade earlier in men, a history of preceding attacks of anginal pain and of hypertension was less common, dyspnea was generally a prominent symptom and a pericardial friction rub was rarely heard. Old infarcts, with absence of actual thrombosis and pericarditis, were more frequent. Sclerosis of the coronary arteries was slightly though not significantly encountered more often. The location of the infarct and the rupture of the ventricular wall, with resulting hemopericardium, bore no direct relation to the absence of pain. The authors have reexamined the old mechanical theory of cardiac pain advocated by Allbutt and Wenckebach and more recently by Herrmann, which has been generally discarded in favor of Lewis's theory of ischemia in the light of their study, and the role of a tension factor has been emphasized. The tension factor seems to offer a reasonable explanation not only for the presence but for the absence of pain in cases of coronary occlusion. Added support for the importance of the factor of tension in the production of cardiac pain has been obtained by an experimental study on animals.

**Longevity.**—Brunie chose for study thirteen men and twelve women active and in good health in the ninth decade of life. The study includes careful medical, dietary and social history, physical examination, blood count, urinalysis, an electrocardiogram and a fluoroscopic examination of the chest. By "active and in good health" he means that these persons were driving their own automobiles, some were still working for a livelihood and many were active in play—trap shooting, going to the races and theater, and even dancing and golf. Most of them took genuine interest in a variety of hobbies. Mentally they were all active and alert. Heredity, without question, is the fundamental requirement for longevity. In the present series there was only one person who did not have immediate relatives—that is, parents or grandparents, brothers or sisters—who had lived or were living beyond 75 years. The incidence of infection in their lives was relatively unimportant. Most of them had had the usual childhood diseases. Three had pneumonia in adult life and four had influenza at the time of the 1918 epidemic. Four gave histories of tonsillitis. One third of the group gave histories of migraine headaches occurring in earlier life, although none of them complained of more than occasional mild headaches at the present time. An interesting endocrine factor is that 60 per cent of the men had retained their sexual powers to an average age of 80 years. This would indicate that their general endocrine systems were

still functioning. There was no case of syphilis and only one mild case of tuberculosis. One person, a man, recovered from pneumonia at the age of 91 years. Study revealed that moderation rather than abstinence was the rule for these people. Obesity shortens life, and none of these people were overweight. True arteriosclerosis was not present in any of the subjects.

**Sublethal Pulmonary Emboli.**—From a study of five cases it is apparent to Kaump and Robinson that the picture in sublethal embolus is exactly that presented by a lethal embolus except for the lesser gravity of the symptoms. The predominant symptoms in sublethal embolus included anxiety of the patient, cough with bloody sputum in one instance, cyanosis, dyspnea, rapid pulse and chest pain. The diagnosis of sublethal embolus must be suspected in the presence of any or all of these symptoms. Occasionally a patient is seen who has only a slight dyspnea, slight chest pain and minor evidences of shock. In the differential diagnosis, coronary thrombosis and pulmonary arteriolar sclerosis must be considered. The predisposing factors in the patients with sublethal embolus include previous heart disease, four out of five, and obesity, three out of five. Next to the prevention of embolus formation the second most important factor is the recognition of sublethal embolus when it does occur. If the symptoms of sublethal embolus were recognized more frequently, simple prolonged rest might prove valuable in the prevention of the second and often fatal embolic attack.

**Availability of Iron in Foods.**—Ascham and her collaborators determined the hematopoietic value of certain leafy vegetables which are important sources of iron in southern diets. They found that a greater hemoglobin gain was obtained with the canned leaves plus the cooking liquid of turnip greens and collards than with the dried forms of these greens. The iron of the canned turnip green leaves was less available than that of the dried greens. The foods studied fall into the following descending order in respect to the availability of their iron for the regeneration of hemoglobin: black-eyed peas and spinach, turnip greens and kale, collards and mustard, head lettuce and, finally, tender-green and leaf lettuce. In these foods the ionizable iron and the iron available for hemoglobin synthesis were not identical.

**Acute Leukemia and Extracts of Bone Marrow.**—Cooke tested the validity of a new hypothesis as to the nature of leukemia. The hypothesis assumes that acute leukemia is due to an acquired defect in normal marrow function charac-

terized by the inactivation or destruction of one of the normal factors in hematopoiesis. After making a few observations with the use of extracts of liver, spleen and thymus, without apparent effect, the action of extracts of fresh red bone marrow on acute leukemia was studied. A study of the patients with acute leukemia treated with bone marrow extracts shows two with complete remission of two and four months, two with similar complete remissions for shorter periods, two with marked increase in maturation of granular leukocytes, four in whom the disease remained clinically arrested or quiescent for from three to six months, two in whom rather prompt decrease in the size of leukemic enlargements of the lymph nodes and spleen was observed after the treatment was given and other patients in whom neither the clinical course nor the leukemic blood picture was affected. That the bone marrow extract employed was responsible for any or all the favorable changes observed is without proof. All patients received transfusions at intervals and other symptomatic treatment. It is true, however, that of fifty patients with acute leukemia from the same clinic and under observation during the ten years preceding these experiments, who were also given frequent transfusions, none showed a remission or any increase in the granular leukocytes to the degree observed in certain of the present patients. The evidence furnished by the observations is inconclusive, but the improvement in at least six cases did not appear to be merely coincidental. However, if the changes observed were related to the replacement of some deficiency in a physiologic mechanism the stimulation was inadequate and incomplete, since even those patients with remissions relapsed and later injections were relatively impotent. The author believes that a definite effect on the disease was produced but that it was only partial and imperfect, as though only one of possibly several necessary substances was being supplied and that only sufficient to modify the progress of the disease.

**Diabetes and Pregnancy.**—Smyth and Olney state that since 1922 nineteen infants have been born of women whose pregnancy was considered complicated by diabetes. In fourteen of the mothers glycosuria appeared only with gestation and was controlled by diet or by diet and temporary use of insulin, which suggests glycosuria from causes other than diabetes mellitus. Of the entire group, eleven gave birth to excessively large infants. The infant's blood sugar, even allowing for the effect of predelivery insulin, may be low. The cord blood sugar may anticipate this finding by showing a much lower level than that of the maternal blood taken simultaneously. In two of the infants projectile vomiting and cyanosis were striking features, quite possibly related to persistent hypoglycemia. This interpretation circumvented pyloroplasty, which was suggested for one of the infants. The use of subcutaneous dextrose appeared extremely valuable in carrying the infants through a critical period, after which an apparent adjustment was made. A follow-up of one patient showed a hyperinsulin-like sugar curve at 4 years of age. Reports of postmortem studies of infants born of diabetic mothers vary. In some no hyperplasia of islet tissue has been found, and the hypoglycemia must be considered functional in type. In others the finding of hypertrophy and hyperplasia of the islets of Langerhans makes the correlation obvious. The relative macrosomia, advanced bone age and more mature genital tract suggest a pituitary effect. Complete endocrine pathologic study is reported but the interrelationship is best described as dysfunction. Perhaps some interrelationship will be found to account for the mild as well as the fatal hypoglycemia of the newborn infant. Fetal glycogen storage hypertrophy also is postulated as a possible cause for some of the pathologic signs.
